MULTILAYERED FLUORESCENT SCREENS FOR SCANNING BEAM DISPLAY SYSTEMS

[0001] This application claims the benefit of U.S. Patent
5 Application No. 11/514,720 entitled "Multilayered Fluorescent
Screens for Scanning Beam Display Systems" and filed August
31, 2006. The Application No. 11/514,720 in turn claims the
benefits of U.S. Provisional Application No. 60/800,870
entitled "Display Systems Using Fluorescent Screens Including
10 Fluorescent Screens With Prismatic Layer" and filed May 15,
2006, and PCT Patent Application No. PCT/US2006/11757 entitled
"Display Systems Having Screens With Optical Fluorescent
Materials" and filed March 31, 2006.

[0002] This application also claims the benefits of (1)
15 U.S. Provisional Application No. 60/800,870 entitled "Display
Systems Using Fluorescent Screens Including Fluorescent
Screens With Prismatic Layer" and filed May 15, 2006, (2) U.S.
Provisional Application No. 60/896,483 entitled "Scanning Beam
Display Systems Using Fluorescent Screens With Reflective
20 Features" and filed March 22, 2007, and (3) U.S. Provisional
Application No. 60/910,797 entitled "Fluorescent Screens With
Metalized Stripe Dividers For Scanning Beam Display Systems"
and filed April 9, 2007.

[0003] The entire disclosures of the above applications are
25 incorporated by reference as part of the specification of this
application.

BACKGROUND

[0004] This application relates to display systems that use
screens with fluorescent materials to emit colored light under
30 optical excitation, such as laser-based image and video
displays and screen designs for such displays.

[0005] Many image and video displays are designed to directly
produce color images in different colors, such as red, green
and blue and then project the color images on a screen. Such
35 systems are often referred to as "projection displays" where
the screen is simply a surface to make the color images

visible to a viewer. Such projection displays may use white light sources where white beams are filtered and modulated to produce images in red, green and blue colors. Alternatively, three light sources in red, green and blue may be used to
5 directly produce three beams in red, green and blue colors and the three beams are modulated to produce images in red, green and blue. Examples of such projection displays include digital light processing (DLP) displays, liquid crystal on silicon (LCoS) displays, and grating light valve (GLV)
10 displays. Notably, GLV displays use three grating light valves to modulate red, green and blue laser beams, respectively, and use a beam scanner to produce the color images on a screen. Another example of laser-based projection displays is described in U.S. Patent No. 5,920,361 entitled
15 "Methods and apparatus for image projection." Projection displays use optical lens systems to image and project the color images on the screen.

[0006] Some other image and video displays use a "direct" configuration where the screen itself includes light-producing
20 color pixels to directly form color images in the screen. Such direct displays eliminate the optical lens systems for projecting the images and therefore can be made relatively smaller than projection displays with the same screen sizes. Examples of direct display systems include plasma displays,
25 liquid crystal displays (LCDs), light-emitting-diode (LED) displays (e.g., organic LED displays), and field-emission displays (FEDs). Each color pixel in such direct displays includes three adjacent color pixels which produce light in red, green and blue, respectively, by either directly emit
30 colored light as in LED displays and FEDs or by filtering white light such as the LCDs.

[0007] These and other displays are replacing cathode-ray tube (CRT) displays which dominated the display markets for decades since its inception. CRT displays use scanning electron beams
35 in a vacuum tube to excite color phosphors in red, green and

blue colors on the screen to emit colored light to produce color images. Although CRT displays can produce vivid colors and bright images with high resolutions, the use of cathode-ray tubes places severe technical limitations on the CRT displays and leads to dramatic decline in demand for CRT displays in recent years.

SUMMARY

[0008] The specification of this application describes, among others, fluorescent screens, and display systems and devices based on such screens using at least one excitation optical beam to excite one or more fluorescent materials on a screen which emit light to form images. The fluorescent materials may include phosphor materials and non-phosphor materials such as quantum dots.

[0009] In one example, a display screen includes parallel screen layers which are engaged to form a planar stack and include a fluorescent layer absorbing excitation light at an excitation wavelength to emit visible light at a different visible wavelength, and a prismatic layer including a plurality of prism elements which receive and couple the excitation light to the fluorescent layer.

[0010] In another example, a display screen includes screen layers which are engaged to form a planar stack and include a fluorescent layer including parallel fluorescent stripes and absorbing excitation light at an excitation wavelength to emit visible light at a different and visible wavelength. The screen layers also include parallel stripe dividers each located between two adjacent fluorescent stripes. Each strip divider includes side walls that are reflective and opaque to the emitted visible light to optically isolate two adjacent fluorescent stripes. A dielectric layer is included to be in contact with the stripe dividers and spaced from the fluorescent layer to form a gap between the dielectric layer and each fluorescent stripe.

[0011] In another example, a display screen includes a screen substrate, and a fluorescent layer formed over the screen substrate to include parallel fluorescent stripes which absorb excitation light to emit visible light. The excitation light and the visible light are at different wavelengths. The display screen also include parallel stripe dividers each located between two adjacent fluorescent stripes, and a dichroic layer formed over the screen substrate to receive the excitation light. The dichroic layer transmits the excitation light and reflects the visible light.

[0012] In another example, a display screen includes a fluorescent layer which includes parallel fluorescent stripes that absorb excitation light to emit visible light. The excitation light and the visible light are at different wavelengths. An entrance layer is formed on a first side of the fluorescent layer to receive the excitation light and to direct the excitation light to the fluorescent layer. A filter layer is also formed a second side of the fluorescent layer opposing the first side. This filter layer is formed of a material that transmits the visible light with an attenuation uniform over a spectral range of the visible light.

[0013] In another example, a display screen includes a fluorescent layer that absorbs excitation light to emit visible light; and a first layer on a first side of the fluorescent layer operable to transmit the excitation light and to reflect the visible light. The first layer includes a prismatic layer which comprises prism elements.

[0014] In another example, a display screen includes a fluorescent layer that absorbs excitation light to emit white light, and an array of color filters adjacent to the fluorescent layer to receive the emitted white light and to filter the white light to transmit colored light. Each color filter transmits a designated color and absorbs light of other colors. Each designated color for one color filter is

different from a designated color transmitted by a neighboring color filter.

[0015] In yet another example, a display screen includes screen layers which are engaged to form a planar stack. The planar stack includes a fluorescent layer comprising parallel fluorescent stripes, parallel stripe dividers each located between two adjacent fluorescent stripes, a dielectric layer in contact with the fluorescent stripes and the stripe dividers to couple the excitation light into the fluorescent stripes, a filter layer comprising parallel filter stripes each aligned to a corresponding fluorescent stripe along a direction perpendicular to the screen layers and positioned to place the fluorescent layer between the dielectric layer and the filter layer, a second dielectric layer between the fluorescent layer and the filter layer, and second parallel stripe dividers each located between two adjacent filter stripes and in contact with the second dielectric layer. The fluorescent layer absorbs excitation light at an excitation wavelength to emit visible light at wavelengths different from the excitation wavelength. Each stripe divider are reflective and opaque to the emitted visible light to optically isolate two adjacent fluorescent stripes. In the filter layer, at least three adjacent filter stripes are respectively made of a first filter material to transmit first visible light of a first color while absorbing light of other colors including a second color and a third color, a second filter material to transmit second visible light of the second color while absorbing light of other colors including the first and the third colors, and a third filter material to transmit third visible light of the third color while absorbing light of the other colors including the first and the second colors.

[0016] In yet another example, a display screen includes a first dielectric layer that transmits excitation light at an excitation wavelength; a fluorescent layer having parallel fluorescent stripes and absorbing the excitation light to emit

visible light at a different and visible wavelength; and a second dielectric layer spaced from the fluorescent stripes by an air gap. The second dielectric layer at least partially transmits the visible light. The fluorescent layer is
5 positioned between the first and second dielectric layers.

[0017] In yet another example, a display screen includes a fluorescent layer comprising parallel fluorescent stripes, and parallel stripe dividers each located between two adjacent fluorescent stripes to separate the two adjacent fluorescent
10 stripes. Each fluorescent stripe emits visible light under illumination of excitation light that optically excites the fluorescent stripe and each stripe divider includes beads that reflect the excitation light as feedback light.

[0018] In yet another example, a display screen includes a
15 fluorescent layer comprising parallel fluorescent stripes, parallel stripe dividers each located between two adjacent fluorescent stripes to separate the two adjacent fluorescent stripes, parallel prism stripes formed over and in alignment with the parallel stripe dividers, respectively. Each
20 fluorescent stripe emits visible light under illumination of excitation light that optically excites the fluorescent stripes. Each prism stripe is structured to reflect the excitation light as feedback light.

[0019] In yet another example, a display screen includes a
25 substrate having a flat surface, parallel fluorescent stripes formed on the flat surface and separated from one another by a gap between two adjacent fluorescent stripes, and a metal coating covering peripheral portions of each of the fluorescent stripes and the gaps over the flat surface between
30 the fluorescent stripes to expose a central portion of each fluorescent stripe.

[0020] Methods of fabricating display screens are disclosed. For example, a method for making a display screen includes forming a plurality of parallel fluorescent stripes on a flat
35 surface of a substrate where the stripes are separated from

one another by a gap between two adjacent fluorescent stripes. A metal coating is deposited to completely cover the fluorescent stripes and to cover the gaps between the fluorescent stripes over the flat surface. A layer of the metal coating and a portion of each fluorescent stripe are removed to expose a central portion of each fluorescent stripe while maintaining at least the metal coating at peripheral portions of each fluorescent stripe.

[0021] These and other examples and implementations are described in detail in the drawings, the detailed description, and the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0022] FIG. 1 shows an example scanning laser display system having a fluorescent screen made of laser-excitatable fluorescent materials (e.g., phosphors) emitting colored lights under excitation of a scanning laser beam that carries the image information to be displayed.

[0023] FIGS. 2A and 2B show one example screen structure and the structure of color pixels on the screen in FIG. 1.

[0024] FIG. 3A shows an example implementation of the laser module in FIG. 1 having multiple lasers that direct multiple laser beams on the screen.

[0025] FIG. 3B shows an example implementation of a post-objective scanning beam display system.

[0026] FIG. 4 illustrates an example screen having a fluorescent stripe layer with fluorescent stripes for emitting red, green and blue colors under optical excitation of the scanning excitation light.

[0027] FIG. 5 shows an example fluorescent layer with fluorescent stripes formed on a supporting substrate.

[0028] FIG. 6 shows an example of a fluorescent screen with two dichroic layers.

[0029] FIGS. 7A and 7B illustrate two screen examples based on the screen design in FIG. 6.

[0030] FIG. 8 shows a fluorescent screen design with a contrast enhancement layer.

[0031] FIG. 9 shows a fluorescent screen design with a contrast enhancement material composition in each fluorescent stripe.

[0032] FIG. 10 illustrates an example of a fluorescent screen design that has a contiguous and uniform layer of mixed phosphors that emits white light.

[0033] FIGS. 11 and 12 show a fluorescent screen design with a Fresnel lens layer to direct scanning input excitation light to the fluorescent screen.

[0034] FIG. 13 shows a prismatic layer as an entrance layer for scanning excitation light in a fluorescent screen.

[0035] FIG. 13A illustrates an operation of the prismatic layer in FIG. 13.

[0036] FIG. 14 shows a high-index layer as an entrance layer for scanning excitation light in a fluorescent screen.

[0037] FIGS. 15, 16, 17, 18, 19, 20, 21, 22, 23, 24 and 25 show various screen designs.

[0038] FIG. 26 shows an implementation of a low-index dielectric layer such as an air gap on the viewer side of the fluorescent layer in a fluorescent screen to improve the image quality of the fluorescent screen.

[0039] FIG. 27 illustrates one example of a fluorescent screen having optically reflective stripe dividers that provide servo feedback light.

[0040] FIG. 28 illustrates one example of reflective stripe dividers for various screen designs in this application.

[0041] FIGS. 29A and 29B illustrate two examples of bead designs for the beads used in the stripe dividers 3720 in FIG. 28.

[0042] FIG. 30 illustrates one example of reflective stripe dividers in FIG. 27 where a prism stripe is placed on top of the dielectric layer over each stripe divider to overlap with the underlying stripe divider.

[0043] FIGS. 31A, 31B and 31C illustrate an example of a screen design with metalized stripe dividers and the fabrication process.

[0044] FIGS. 32 and 33 shows examples of screens having
5 metalized stripe dividers based on the design in FIGS. 31A, 31B and 31C.

[0045] FIG. 34 shows an example of a screen with metalized stripe dividers containing reflective beads.

DETAILED DESCRIPTION

10 **[0046]** This application describes scanning beam display systems that use screens with fluorescent materials to emit light under optical excitation to produce images, including laser video display systems. Various examples of screen designs with fluorescent materials are described. Screens
15 with phosphor materials under excitation of one or more scanning excitation laser beams are described in detail and are used as specific implementation examples of optically excited fluorescent materials in various system and device examples in this application.

20 **[0047]** In one implementation, for example, three different color phosphors that are optically excitable by the laser beam to respectively produce light in red, green, and blue colors suitable for forming color images may be formed on the screen as pixel dots or repetitive red, green and blue phosphor
25 stripes in parallel. Various examples described in this application use screens with parallel color phosphor stripes for emitting light in red, green, and blue to illustrate various features of the laser-based displays.

[0048] Phosphor materials are one type of fluorescent
30 materials. Various described systems, devices and features in the examples that use phosphors as the fluorescent materials are applicable to displays with screens made of other optically excitable, light-emitting, non-phosphor fluorescent materials. For example, quantum dot materials emit light
35 under proper optical excitation and thus can be used as the

fluorescent materials for systems and devices in this application. More specifically, semiconductor compounds such as, among others, CdSe and PbS, can be fabricated in form of particles with a diameter on the order of the exciton Bohr
5 radius of the compounds as quantum dot materials to emit light. To produce light of different colors, different quantum dot materials with different energy band gap structures may be used to emit different colors under the same excitation light. Some quantum dots are between 2 and 10
10 nanometers in size and include approximately tens of atoms such between 10 to 50 atoms. Quantum dots may be dispersed and mixed in various materials to form liquid solutions, powders, jelly-like matrix materials and solids (e.g., solid solutions). Quantum dot films or film stripes may be formed
15 on a substrate as a screen for a system or device in this application. In one implementation, for example, three different quantum dot materials can be designed and engineered to be optically excited by the scanning laser beam as the optical pump to produce light in red, green, and blue colors
20 suitable for forming color images. Such quantum dots may be formed on the screen as pixel dots arranged in parallel lines (e.g., repetitive sequential red pixel dot line, green pixel dot line and blue pixel dot line).

[0049] Examples of scanning beam display systems described
25 here use at least one scanning laser beam to excite color light-emitting materials deposited on a screen to produce color images. The scanning laser beam is modulated to carry images in red, green and blue colors or in other visible colors and is controlled in such a way that the laser beam
30 excites the color light-emitting materials in red, green and blue colors with images in red, green and blue colors, respectively. Hence, the scanning laser beam carries the images but does not directly produce the visible light seen by a viewer. Instead, the color light-emitting fluorescent
35 materials on the screen absorb the energy of the scanning

laser beam and emit visible light in red, green and blue or other colors to generate actual color images seen by the viewer.

[0050] Laser excitation of the fluorescent materials using one or more laser beams with energy sufficient to cause the fluorescent materials to emit light or to luminesce is one of various forms of optical excitation. In other implementations, the optical excitation may be generated by a non-laser light source that is sufficiently energetic to excite the fluorescent materials used in the screen. Examples of non-laser excitation light sources include various light-emitting diodes (LEDs), light lamps and other light sources that produce light at a wavelength or a spectral band to excite a fluorescent material that converts the light of a higher energy into light of lower energy in the visible range. The excitation optical beam that excites a fluorescent material on the screen can be at a frequency or in a spectral range that is higher in frequency than the frequency of the emitted visible light by the fluorescent material. Accordingly, the excitation optical beam may be in the violet spectral range and the ultra violet (UV) spectral range, e.g., wavelengths under 420 nm. In the examples described below, UV light or a UV laser beam is used as an example of the excitation light for a phosphor material or other fluorescent material and may be light at other wavelength.

[0051] FIG. 1 illustrates an example of a laser-based display system using a screen having color phosphor stripes. Alternatively, color phosphor dots may also be used to define the image pixels on the screen. The system includes a laser module 110 to produce and project at least one scanning laser beam 120 onto a screen 101. The screen 101 has parallel color phosphor stripes in the vertical direction where red phosphor absorbs the laser light to emit light in red, green phosphor absorbs the laser light to emit light in green and blue phosphor absorbs the laser light to emit light in blue.

Adjacent three color phosphor stripes are in three different colors. One particular spatial color sequence of the stripes is shown in FIG. 1 as red, green and blue. Other color sequences may also be used. The laser beam 120 is at the wavelength within the optical absorption bandwidth of the color phosphors and is usually at a wavelength shorter than the visible blue and the green and red colors for the color images. As an example, the color phosphors may be phosphors that absorb UV light in the spectral range from about 380 nm to about 420 nm to produce desired red, green and blue light. The laser module 110 can include one or more lasers such as UV diode lasers to produce the beam 120, a beam scanning mechanism to scan the beam 120 horizontally and vertically to render one image frame at a time on the screen 101, and a signal modulation mechanism to modulate the beam 120 to carry the information for image channels for red, green and blue colors. Such display systems may be configured as rear projection systems where the viewer and the laser module 110 are on the opposite sides of the screen 101. Alternatively, such display systems may be configured as front projection systems where the viewer and laser module 110 are on the same side of the screen 101.

[0052] FIG. 2A shows an exemplary design of the screen 101 in FIG. 1. The screen 101 may include a rear substrate 201 which is transparent to the scanning laser beam 120 and faces the laser module 110 to receive the scanning laser beam 120. A second front substrate 202, is fixed relative to the rear substrate 201 and faces the viewer in a rear projection configuration. A color phosphor stripe layer 203 is placed between the substrates 201 and 202 and includes phosphor stripes. The color phosphor stripes for emitting red, green and blue colors are represented by "R", "G" and "B," respectively. The front substrate 202 is transparent to the red, green and blue colors emitted by the phosphor stripes. The substrates 201 and 202 may be made of various materials,

including glass or plastic panels. Each color pixel includes portions of three adjacent color phosphor stripes in the horizontal direction and its vertical dimension is defined by the beam spread of the laser beam 120 in the vertical
5 direction. As such, each color pixel includes three subpixels of three different colors (e.g., the red, green and blue). The laser module 110 scans the laser beam 120 one horizontal line at a time, e.g., from left to right and from top to bottom to fill the screen 101. The laser module 110 is fixed
10 in position relative to the screen 101 so that the scanning of the beam 120 can be controlled in a predetermined manner to ensure proper alignment between the laser beam 120 and each pixel position on the screen 101.

[0053] In FIG. 2A, the scanning laser beam 120 is directed at
15 the green phosphor stripe within a pixel to produce green light for that pixel. FIG. 2B further shows the operation of the screen 101 in a view along the direction B-B perpendicular to the surface of the screen 101. Since each color stripe is longitudinal in shape, the cross section of the beam 120 may
20 be shaped to be elongated along the direction of the stripe to maximize the fill factor of the beam within each color stripe for a pixel. This may be achieved by using a beam shaping optical element in the laser module 110. A laser source that is used to produce a scanning laser beam that excites a
25 phosphor material on the screen may be a single mode laser or a multimode laser. The laser may also be a single mode along the direction perpendicular to the elongated direction phosphor stripes to have a small beam spread that is confined by the width of each phosphor stripe. Along the elongated
30 direction of the phosphor stripes, this laser beam may have multiple modes to spread over a larger area than the beam spread in the direction across the phosphor stripe. This use of a laser beam with a single mode in one direction to have a small beam footprint on the screen and multiple modes in the
35 perpendicular direction to have a larger footprint on the

screen allows the beam to be shaped to fit the elongated color subpixel on the screen and to provide sufficient laser power in the beam via the multimodes to ensure sufficient brightness of the screen.

5 **[0054]** Each of the fluorescent stripes in the fluorescent screen 101 in various examples described in this application is a fluorescent stripe that emits a designated color under optical excitation and can be a fluorescent stripe formed of a particular fluorescent material that emits the designed color
10 as shown in the example in FIG. 2A. Alternatively, a fluorescent stripe can be constructed by a combination of a stripe color filter over a contiguous and uniform white fluorescent layer that is made of mixed phosphors that emit white light under optical excitation of the excitation light
15 120. Hence, a filter layer of color filters, such as stripes of red-transmitting, green-transmitting and blue-transmitting filters, is placed on the viewer side of the mixed phosphor layer to filter the white light and to produce colored output light. The details of the construction of the fluorescent
20 stripes are described in a later section of this specification with reference to FIG. 10. In this context, a fluorescent layer has a composite structure with a filter layer and a contiguous fluorescent layer that emits white light.

[0055] Referring now to FIG. 3A, an example implementation of
25 the laser module 110 in FIG. 1 is illustrated. A laser array 310 with multiple lasers is used to generate multiple laser beams 312 to simultaneously scan the screen 101 for enhanced display brightness. A signal modulation controller 320 is provided to control and modulate the lasers in the laser array
30 310 so that the laser beams 312 are modulated to carry the image to be displayed on the screen 101. The signal modulation controller 320 can include a digital image processor that generates digital image signals for the three different color channels and laser driver circuits that
35 produce laser control signals carrying the digital image

signals. The laser control signals are then applied to modulate the lasers, e.g., the currents for laser diodes, in the laser array 310.

[0056] The beam scanning can be achieved by using a scanning mirror 340 such as a galvo mirror for the vertical scanning and a multi-facet polygon scanner 350 for the horizontal scanning. A scan lens 360 can be used to project the scanning beams from the polygon scanner 350 onto the screen 101. The scan lens 360 is designed to image each laser in the laser array 310 onto the screen 101. Each of the different reflective facets of the polygon scanner 350 simultaneously scans N horizontal lines where N is the number of lasers. In the illustrated example, the laser beams are first directed to the galvo mirror 340 and then from the galvo mirror 340 to the polygon scanner 350. The output scanning beams 120 are then projected onto the screen 101. A relay optics module 330 is placed in the optical path of the laser beams 312 to modify the spatial property of the laser beams 312 and to produce a closely packed bundle of beams 332 for scanning by the galvo mirror 340 and the polygon scanner 350 as the scanning beams 120 projected onto the screen 101 to excite the phosphors and to generate the images by colored light emitted by the phosphors.

[0057] The laser beams 120 are scanned spatially across the screen 101 to hit different color pixels at different times. Accordingly, each of the modulated beams 120 carries the image signals for the red, green and blue colors for each pixel at different times and for different pixels at different times. Hence, the beams 120 are coded with image information for different pixels at different times by the signal modulation controller 320. The beam scanning thus maps the time-domain coded image signals in the beams 120 onto the spatial pixels on the screen 101. For example, the modulated laser beams 120 can have each color pixel time equally divided into three sequential time slots for the three color subpixels for the

three different color channels. The modulation of the beams 120 may use pulse modulation techniques to produce desired grey scales in each color, a proper color combination in each pixel, and desired image brightness.

5 **[0058]** In one implementation, the multiple beams 120 are directed onto the screen 101 at different and adjacent vertical positions with two adjacent beams being spaced from each other on the screen 101 by one horizontal line of the screen 101 along the vertical direction. For a given position
10 of the galvo mirror 340 and a given position of the polygon scanner 350, the beams 120 may not be aligned with each other along the vertical direction on the screen 101 and may be at different positions on the screen 101 along the horizontal direction. The beams 120 can only cover one portion of the
15 screen 101. At a fixed angular position of the galvo mirror 340, the spinning of the polygon scanner 350 causes the beams 120 from N lasers in the laser array 310 to scan one screen segment of N adjacent horizontal lines on the screen 101. At end of each horizontal scan over one screen segment, the galvo
20 mirror 340 is adjusted to a different fixed angular position so that the vertical positions of all N beams 120 are adjusted to scan the next adjacent screen segment of N horizontal lines. This process iterates until the entire screen 101 is scanned to produce a full screen display.

25 **[0059]** In the above example of a scanning beam display system shown in FIG. 3A, the scan lens 360 is located downstream from the beam scanning devices 340 and 350 and focuses the one or more scanning excitation beams 120 onto the screen 101. This optical configuration is referred to as a
30 "pre-objective" scanning system. In such a pre-objective design, a scanning beam directed into the scan lens 360 is scanned along two orthogonal directions. Therefore, the scan lens 360 is designed to focus the scanning beam onto the screen 101 along two orthogonal directions. In order to
35 achieve the proper focusing in both orthogonal directions, the

scan lens 360 can be complex and, often, are made of multiples lens elements. In one implementation, for example, the scan lens 360 can be a two-dimensional f-theta lens that is designed to have a linear relation between the location of the focal spot on the screen and the input scan angle (θ) when the input beam is scanned around each of two orthogonal axes perpendicular to the optic axis of the scan lens. In such a f-theta lens, the location of the focal spot on the screen is a proportional to the input scan angle (θ).

10 **[0060]** The two-dimensional scan lens 360 such as a f-theta lens in the pre-objective configuration can exhibit optical distortions along the two orthogonal scanning directions which cause beam positions on the screen 101 to trace a curved line. Hence, an intended straight horizontal scanning line on the screen 101 becomes a curved line. The distortions caused by the 2-dimensional scan lens 360 can be visible on the screen 101 and thus degrade the displayed image quality. One way to mitigate the bow distortion problem is to design the scan lens 360 with a complex lens configuration with multiple lens elements to reduce the bow distortions. The complex multiple lens elements can cause the final lens assembly to depart from desired f-theta conditions and thus can compromise the optical scanning performance. The number of lens elements in the assembly usually increases as the tolerance for the distortions decreases. However, such a scan lens with complex multiple lens elements can be expensive to fabricate.

25 **[0061]** To avoid the above distortion issues associated with a two-dimensional scan lens in a pre-objective scanning beam system, the following sections describe examples of a post-objective scanning beam display system, which can be implemented to replace the two-dimensional scan lens 360 with a simpler, less expensive 1-dimensional scan lens. U.S. Patent Application No. 11/742,014 entitled "POST-OBJECTIVE SCANNING BEAM SYSTEMS" and filed on April 30, 2007 (U.S. Patent Publication No. _____) describes examples of

post-objective scanning beam systems suitable for use with phosphor screens described in this application and is incorporated by reference as part of the specification of this application. The screen designs described in this application
5 can be used in both post-objective and pre-objective scanning beam display systems.

[0062] FIG. 3B shows an example implementation of a post-objective scanning beam display system based on the system design in FIG. 1. A laser array 310 with multiple lasers is
10 used to generate multiple laser beams 312 to simultaneously scan a screen 101 for enhanced display brightness. A signal modulation controller 320 is provided to control and modulate the lasers in the laser array 310 so that the laser beams 312 are modulated to carry the image to be displayed on the screen
15 101. The beam scanning is based on a two-scanner design with a horizontal scanner such as a polygon scanner 350 and a vertical scanner such as a galvanometer scanner 340. Each of the different reflective facets of the polygon scanner 350 simultaneously scans N horizontal lines where N is the number
20 of lasers. A relay optics module 330 reduces the spacing of laser beams 312 to form a compact set of laser beams 332 that spread within the facet dimension of the polygon scanner 350 for the horizontal scanning. Downstream from the polygon scanner 350, there is a 1-D horizontal scan lens 380 followed
25 by a vertical scanner 340 (e.g., a galvo mirror) that receives each horizontally scanned beam 332 from the polygon scanner 350 through the 1-D scan lens 380 and provides the vertical scan on each horizontally scanned beam 332 at the end of each horizontal scan prior to the next horizontal scan by the next
30 facet of the polygon scanner 350. The vertical scanner 340 directs the 2-D scanning beams 390 to the screen 101.

[0063] Under this optical design of the horizontal and vertical scanning, the 1-D scan lens 380 is placed downstream from the polygon scanner 140 and upstream from the vertical
35 scanner 340 to focus each horizontal scanned beam on the

screen 101 and minimizes the horizontal bow distortion to displayed images on the screen 101 within an acceptable range, thus producing a visually "straight" horizontal scan line on the screen 101. Such a 1-D scan lens 380 capable of producing
5 a straight horizontal scan line is relatively simpler and less expensive than a 2-D scan lens of similar performance. Downstream from the scan lens 380, the vertical scanner 340 is a flat reflector and simply reflects the beam to the screen 101 and scans vertically to place each horizontally scanned
10 beam at different vertical positions on the screen 101 for scanning different horizontal lines. The dimension of the reflector on the vertical scanner 340 along the horizontal direction is sufficiently large to cover the spatial extent of each scanning beam coming from the polygon scanner 350 and the
15 scan lens 380. The system in FIG. 3B is a post-objective design because the 1-D scan lens 380 is upstream from the vertical scanner 340. In this particular example, there is no lens or other focusing element downstream from the vertical scanner 340.

20 **[0064]** Notably, in the post-objective system in FIG. 3B, the distance from the scan lens to a location on the screen 101 for a particular beam varies with the vertical scanning position of the vertical scanner 340. Therefore, when the 1-D scan lens 380 is designed to have a fixed focal distance along
25 the straight horizontal line across the center of the elongated 1-D scan lens, the focal properties of each beam must change with the vertical scanning position of the vertical scanner 380 to maintain consistent beam focusing on the screen 101. In this regard, a dynamic focusing mechanism
30 can be implemented to adjust convergence of the beam going into the 1-D scan lens 380 based on the vertical scanning position of the vertical scanner 340.

[0065] For example, in the optical path of the one or more laser beams from the lasers to the polygon scanner 350, a
35 stationary lens and a dynamic refocus lens can be used as the

dynamic focusing mechanism. Each beam is focused by the dynamic focus lens at a location upstream from the stationary lens. When the focal point of the lens coincides with the focal point of the lens, the output light from the lens is collimated. Depending on the direction and amount of the deviation between the focal points of the lenses, the output light from the collimator lens toward the polygon scanner 350 can be either divergent or convergent. Hence, as the relative positions of the two lenses along their optic axis are adjusted, the focus of the scanned light on the screen 101 can be adjusted. A refocusing lens actuator can be used to adjust the relative position between the lenses in response to a control signal. In this particular example, the refocusing lens actuator is used to adjust the convergence of the beam directed into the 1-D scan lens 380 along the optical path from the polygon scanner 350 in synchronization with the vertical scanning of the vertical scanner 340. The vertical scanner 340 in FIG. 3B scans at a much smaller rate than the scan rate of the first horizontal scanner 350 and thus a focusing variation caused by the vertical scanning on the screen 101 varies with time at the slower vertical scanning rate. This allows a focusing adjustment mechanism to be implemented in the system of FIG. 1 with the lower limit of a response speed at the slower vertical scanning rate rather than the high horizontal scanning rate.

[0066] The stripe design in FIG. 2B for the fluorescent screen 101 in FIGS. 1, 3A and 3B can be implemented in various configurations. FIG. 2A shows one example which places the fluorescent layer 203 such as a color phosphor stripe layer between two substrates 201 and 202. In a rear projection system, it is desirable that the screen 101 couple as much light as possible in the incident scanning excitation beam 120 into the fluorescent layer while maximizing the amount of the emitted light from the fluorescent layer that is directed towards the viewer side. A number of screen mechanisms can be

implemented, either individually or in combination, in the screen 101 to enhance the screen performance, including efficient collection of the excitation light, maximization of fluorescent light directed towards the viewer side,

5 enhancement of the screen contrast and reduction the screen glare. The structure and materials of the screen 101 can be designed and selected to meet constraints on cost and other requirements for specific applications.

[0067] FIG. 4 illustrates an example screen 101 having a
10 fluorescent stripe layer with fluorescent stripes for emitting red, green and blue colors under optical excitation of the scanning excitation light. A number of screen features are illustrated as examples and can be selectively implemented in specific screens. Hence, a particular fluorescent screen
15 having only some of the features illustrated in FIG. 4 may be sufficient for a particular display application.

[0068] The fluorescent screen 101 in FIG. 4 includes at least one substrate layer 424 to provide a rigid structural support for various screen components including a fluorescent
20 layer 400. This substrate layer 424 can be a thin substrate or a rigid sheet. When placed on the viewer side of the fluorescent layer 400 as illustrated in FIG. 4, the substrate layer 424 can be made of a material transparent or partially transparent to the visible colored light emitted by the
25 fluorescent stripes 401, 402, 403. A partial transparent material can have a uniform attenuation to the visible light including the three colors emitted by the fluorescent stripes to operate like an optical neutral density filter. The substrate layer 424 can be made of a plastic material, a glass
30 material, or other suitable dielectric material. For example, the substrate layer 424 may be made of an acrylic rigid sheet. The thickness of the substrate layer 424 may be a few millimeters in some designs. In addition, the substrate layer 424 may be made reflective and opaque to the excitation light
35 of the excitation beam 120 to block the excitation light from

reaching the viewer and to recycle the unabsorbed excitation light back to the fluorescent layer 400.

[0069] The substrate layer 424 can also be located on the other side of the fluorescent layer 400. Because the
5 excitation beam 120 must transmit through the substrate layer 424 to enter the fluorescent layer 400, the material for the substrate layer 424 should be transparent to the excitation light of the excitation beam 120. In addition, the substrate layer 424 in this configuration may also be reflective to the
10 visible light emitted by the fluorescent layer 400 to direct any emitted visible light coming from the fluorescent layer 400 towards the viewer side to improve the brightness of the displayed images.

[0070] The fluorescent layer 400 includes parallel
15 fluorescent stripes with repetitive color patterns such as red, green and blue phosphor stripes. The fluorescent stripes are perpendicular to the horizontal scan direction of the scanning excitation beam 120 shown in FIG. 1. As illustrated in FIG. 4 and in FIG. 2B, each display pixel on the screen
20 includes three subpixels which are portions of adjacent red, green and blue stripes 401, 402 and 402. The dimension of each subpixel along the horizontal direction is defined by the width of each stripe and the dimension along the vertical direction is defined by the beam width along the vertical
25 direction. A stripe divider 404, which can be optically reflective and opaque, or optically absorbent, may be formed between any two adjacent fluorescent stripes to minimize or reduce the cross talk between two adjacent subpixels. As a result, the smearing at a boundary between two adjacent
30 subpixels within one color pixel and between two adjacent color pixels can be reduced, and the resolution and contrast of the screen can be improved. The sidewalls of each stripe divider 404 can be made optically reflective to improve the brightness of each subpixel and the efficiency of the screen.

[0071] The above basic structure of the substrate layer 424 and the fluorescent layer 400 can be used as a building block to add one or more screen elements to enhance various properties and the performance of the screen. The fluorescent layer 400 is an optically active layer in the context that the excitation light at the excitation wavelength is absorbed by the fluorescent materials and is converted into visible fluorescent light of different colors for displaying the images to the viewer. In this regard, the fluorescent layer 400 is also the division between the "excitation side" and the "viewer side" of the screen where the optical properties of the two sides are designed very differently in order to achieve desired optical effects in each of two sides to enhance the screen performance. Examples of such optical effects include, enhancing coupling of the excitation beam 120 into the fluorescent layer, recycling reflected and scattered excitation light that is not absorbed by the fluorescent layer 400 back into the fluorescent layer 400, maximizing the amount of the emitted visible light from the fluorescent layer 400 towards the viewer side of the screen, reducing screen glare to the viewer caused by reflection of the ambient light, blocking the excitation light from existing the screen towards the viewer, and enhancing the contrast of the screen. Various screen elements can be configured to achieve one or more of these optical effects. Several examples of such screen elements are illustrated in FIG. 4.

[0072] Referring to FIG. 4, at the entry side of the screen facing the excitation beam 120, an entrance layer 411 can be provided to couple the excitation beam 120 into the screen 101. A Fresnel lens layer can be used as this entrance layer 411 to control the incidence direction of the scanning excitation beam 120. A prismatic layer or a high-index dielectric layer can also be used as part of the entrance layer 411 to recycle light back into the screen including the excitation light and the emitted visible light by the

fluorescent layer. To improve the brightness of the screen to the viewer, a first dichroic layer 412 (D1) can be placed in the path of the excitation beam 120 upstream from the fluorescent layer 400 to transmit light at the wavelength of the excitation beam 120 and to reflect visible light emitted by the fluorescent layer 400. The first dichroic layer 412 can reduce the optical loss of the fluorescent light and thus enhances the screen brightness. On the viewer side of the fluorescent layer 400, a second dichroic layer 421 (D2) can be provided to transmit the visible light emitted by the fluorescent layer 400 and to reflect light at the wavelength of the excitation beam 120. Hence, the second dichroic layer 421 can recycle the excitation light that passes through the fluorescent layer 400 back to the fluorescent layer 400 and thus increases the utilization efficiency of the excitation light and the screen brightness.

[0073] On the viewer side of the fluorescent layer 400, a contrast enhancement layer 422 can be included to improve the screen contrast. The contrast enhancement layer 422 can include color-selective absorbing stripes that spatially correspond to and align with fluorescent stripes in the fluorescent layer 400 along the direction perpendicular to the screen layers. The color-selective absorbing stripes therefore transmit light in respective colors of the fluorescent stripes and absorb light in colors of other fluorescent stripes, respectively. Alternatively, the contrast enhancement layer 422 can be an optical neutral density filter layer that uniformly attenuates the visible light to reduce the glare of the screen due to the reflection of the ambient light. This neutral density filtering function may also be implemented in one or more other layers on the viewer side of the fluorescent layer 400, including the substrate layer 424.

[0074] In addition, the screen can include a screen gain layer 423 on the viewer side of the fluorescent layer 400 to

optically enhance the brightness and viewing angle of the screen. The gain layer 423 may include a lenticular layer with lens elements, a diffractive optic layer of diffractive elements, a holographic layer with holographic elements, or a combination of these and other structures. The spatial sequence of the layers 423, 422 and 421 on the viewer side of the fluorescent layer 400 may be different from what is shown in FIG. 4.

[0075] Furthermore, an excitation blocking layer 425 can be placed on the viewer side of the fluorescent layer 400 to block any excitation light from exiting the screen to the viewer side. This layer can be implemented by a material that transmits the visible light and absorbs the excitation light. For example, a polyester based color filter can be used as this layer to block the excitation light which may be radiation from 400-415 nm. In some implementations, this blocking filter may have transmission below 410nm less than 0.01%, while having greater than 50% transmission above 430 nm. The neutral density filtering function can also be incorporated in this layer, e.g., having a uniform attenuation to the visible light between 430 nm and 670 nm. This blocking function can be incorporated into the substrate layer 424.

[0076] FIG. 5 shows an example fluorescent layer 400 formed on a supporting substrate 501. The fluorescent layer 400 has fluorescent stripes where adjacent three stripes are 401, 402, 403 for emitting red, green and blue colors, respectively. The supporting substrate 501 includes parallel raised lands 502 as stripe dividers to divide the surface into parallel channels in which the fluorescent materials are placed to form the fluorescent stripes 401, 402, 403, etc. The sidewalls of the raised lands 502 physically separate the different fluorescent stripes and can be made optically reflective and opaque to block crosstalk or color mixing between two adjacent fluorescent stripes that emit two different colors, respectively. The reflective sidewalls of the raised lands

502 prevent loss of light emitted in each fluorescent stripe. In addition, the parallel channels formed between the raised lands 502 can be used to control the volume of the fluorescent material deposited during the formation of the fluorescent layer.

[0077] FIG. 6 shows an example of a fluorescent screen with two dichroic layers 412 and 421. A fluorescent layer 610 includes different fluorescent or phosphor layers for different colors are formed at different layers and do not overlap with one another. As illustrated, each layer includes patterned phosphor regions of the same phosphor for one color and non-phosphor regions 620 with a filler material that is transparent. The dividers 404 for reducing color crosstalk may be physically printed with color phosphors, or contained in separate layers. The multi-layer structure of the fluorescent layer 610 may be implemented in different configurations. For example, a host substrate can be used to support different phosphors where non-overlapping phosphor patterns are coated on either side of the substrate. This design of the phosphor layers allows different phosphor layers to be individually fabricated and laminated together by, e.g., using a suitable optical adhesive or an optical pressure-sensitive film. A substrate or rigid sheet 630 is located on the excitation side of the fluorescent layer 610 to support the various layers of the screen and can be made from, e.g., acrylic, rigid optical plastic material, a stretched membrane, and a glass material. An anti-reflection (AR) layer 640 can be formed on the surface of the substrate 630 through which the excitation beam 120 enters the screen.

[0078] Turning now specifically to the dichroic layers 412 and 421 in FIG. 4, the first dichroic layer D1 412 can prevent loss of light emitted from the fluorescent layer 400 towards the excitation side and reflect the emitted light towards the viewer side. The second dichroic layer 421 (D2) is to transmit the visible light and to reflect light at the

wavelength of the excitation laser light 120. This screen design with the two dichroic layers 412 and 421 can effectively confine the excitation light such as UV light within the fluorescent layer 400 so that the unabsorbed excitation light, after passing through the fluorescent layer 400, is reflected back by the dichroic layer 421 (D2) to continue interacting with the fluorescent materials in the fluorescent layer 400 to improve the utility efficiency of the excitation light. In addition, the visible light emitted by the fluorescent layer 400, which originally tends to be in all directions, is directed by the dichroic layer 412 (D1) towards the viewer side of the screen to be viewed by a viewer without leaking to the excitation side of the screen. Accordingly, the overall utility efficiency of the emitted light and the brightness of the screen can be enhanced.

[0079] FIGS. 7A and 7B illustrate two screen examples based on the above screen design. A substrate 701 is provided to support the dichroic layers 412, 421 and the fluorescent layer 400. FIG. 7A shows an example where the substrate 701 is on the side of the dichroic layer 421 so that the emitted light exits the screen through the substrate 701. FIG. 7B shows an example where the substrate 701 is on the side of the dichroic layer 412 and the incident excitation beam 120 enters the screen through the substrate 701. In one example, the excitation beam 120 can be UV laser light around 405 nm. The D1 layer 412 reflects visible light with a wavelength greater than 430 nm and transmits UV light with a wavelength shorter than 415 nm or 400 nm. In this example, the D2 layer 421 reflects UV light with a wavelength shorter than 415 nm or even less than 400 nm and transmits visible light with a wavelength greater than 430 nm. Anti-reflection (AR) coatings may be used to further enhance the efficiency of the screen.

[0080] The configuration in FIG. 7A provides better transmission properties for the excitation light such as UV light, a minimum back reflection towards the excitation side,

and allows the substrate 701 to act as a shield from the user interface side. The configuration in FIG. 7B allows the substrate 701 to be treated to form an optical diffractive element and other optical features in the entrance layer 411 to improve the coupling and recycling of the excitation light. A hard protective surface, e.g., a lacquer layer or capsulation layer may be formed on the viewer or user side of the screen to protect the screen from handling and environmental conditions.

15

[0081] TABLE 1 shows four examples of 6-layer screens where the layers are labeled 1 through 6 in the spatial order from the excitation side to the viewer side of the screen. One or more phosphors are used to form the fluorescent layer and a capsulation layer such as a lacquer layer (L) is used to protect the overall screen structure from handling and environmental conditions. The substrate may be made of a plastic or glass material and, when located on the viewer side of the fluorescent layer, is capable of transmitting light in the spectral range of the visible light, e.g., 400-800 nm. Anti-reflective (AR) coating layers are also included in these examples.

[0082] Each of the above dichroic layers D1 (412) and D2 (421) may be implemented in various configurations. For large format displays, such a dichroic layer may be made of

30

relatively inexpensive materials and be relatively easy to manufacture. Multiple dielectric layers can be designed to construct various wavelength-selective optical filters by controlling the refractive indices and the physical thickness values of the layers. For example, multiple layers of alternating high and low index dielectric layers may be designed to achieve desired wavelength-selective reflection and transmission spectra. Multiple sheets of films with different refractive indices may be laminated or fused together to construct a composite sheet as the D1 or D2 dichroic layer. In some implementations, multiple layers of two different materials with different indices may be used to form a composite film stack as D1 or D2 by placing the two materials in an alternating manner. In other implementations, three or more different materials with different indices may be stacked together to form the composite film stack as D1 or D2. Such a composite sheet for the D1 layer is essentially an optical interference reflector that transmits the excitation light (e.g., UV light) and reflects the colored visible light. The materials for the composite sheets may be organic materials, inorganic materials or a combination of organic and inorganic materials that can be rigid or flexible.

[0083] A flexible multi-layer composite sheet may be formed from polymeric, non-polymeric materials, or polymeric and non-polymeric materials. Exemplary films including a polymeric and non-polymeric material are disclosed in U.S. Patent No. 6,010,751 entitled "Method for forming a multicolor interference coating" and U.S. Patent No. 6,172,810 entitled "Retroreflective articles having polymer multilayer reflective coatings," which are incorporated by reference in their entirety as part of the specification of this application. An all-polymer construction for a composite sheet can offer manufacturing and cost benefits. High temperature polymers with high optical transmission and large index differentials can be used to construct the interference filter that is

environmentally stable, thin and flexible. Coextruded multilayer interference filters as disclosed in U.S. Patent No. 6,531,230 entitled "Color shifting film" can be used to provide precise wavelength selection and can be made as a filter film in a large area at a relatively low cost. The entire disclosure of U.S. Patent No. 6,531,230 is incorporated by reference as part of the specification of this application. The use of polymer pairs having high index differentials allows the construction of thin, highly reflective mirrors that are freestanding without a substrate and can be easily processed for constructing large screens. Such a composite sheet is functionally a piece of a multi-layer optical film (MOF) which can be, e.g., a stack of alternating layers of PET and co-PMMA to exhibit a normal-incidence reflection band suitable for screen applications. As an example, an enhanced specular reflector (ESR) made out of a multilayer polyester-based film from 3M Corporation may be configured to produce the desired dichroic reflection and transmission bands for the present application. Examples for various features of multi-layer films are described in U.S. Patent No. 5,976,424 entitled "Method for making multilayer optical films having thin optical layers," U.S. Patent No. 5,080,467 entitled "Biphenyl derivatives for photostabilization in pulsed optical darkening apparatus and method" and U.S. Patent No. 6,905,220 entitled "Backlight system with multilayer optical film reflector," all of which are incorporated by reference as part of the specification of this application.

[0084] The stripe dividers shown in FIGS. 4, 5 and 6 provide physical separation and optical isolation between different subpixels and can enhance the image contrast by reducing crosstalk between different subpixels and different pixels. Such crosstalks are caused by the internal structure of the screen. Various external factors can also adversely affect the image contrast and other performance parameters of the screens. For example, a portion of the ambient light can

be reflected off the screen and enter a viewer's eyes along with the displayed image formed by the emitted fluorescent light. This reflection of the ambient light towards the viewer generates a glare on the screen to the viewer and can
5 reduce the contrast of the image perceived by the viewer. A contrast enhancement layer, such as the layer 422 in FIG. 4, can be used to reduce the glare.

[0085] FIG. 8 shows one example of a screen 800 that uses a contrast enhancement layer 810 on the viewer side of the
10 fluorescent layer 820. The fluorescent layer 820 such as a phosphor layer includes parallel phosphor stripes. Accordingly, the contrast enhancement layer 810 also includes matching parallel stripes made of different materials. For a red phosphor stripe 821 that emits red light in response to
15 excitation by the excitation light (e.g., UV or violet light), the matching stripe 811 in the contrast enhancement layer 810 is made of a "red" material that transmits in a red spectral band covering the red light emitted by the red phosphor stripe 821 and absorbs or otherwise blocks other visible light
20 including the green and blue light. Similarly, for a green phosphor stripe that emits green light in response to excitation by UV light, the matching stripe in the contrast enhancement layer 810 is made of a "green" material that transmits in a green spectral band covering the green light
25 emitted by the green phosphor and absorbs or otherwise blocks other visible light including the red and blue light. For a blue phosphor stripe that emits blue light in response to excitation by UV light, the matching stripe in the contrast enhancement layer 810 is made of a "blue" material that
30 transmits in a blue spectral band covering the blue light emitted by the blue phosphor and absorbs or otherwise blocks other visible light including the green and red light. These matching parallel stripes in the contrast enhancement layer 810 are labeled as "R," "G" and "B," respectively.

[0086] In this example, the contrast enhancement layer 810 includes different stripe filtering regions that spatially align with and match respective fluorescent regions along the direction perpendicular to the screen. Each filtering region transmits light of a color that is emitted by a corresponding matching fluorescent region and blocks light of other colors. Different filtering regions in the layer 810 may be made of materials that absorb light of other colors different from the colors emitted by the respective matching fluorescent regions. Examples of suitable materials include dye-based colorants and pigment-based colorants. In addition, each filtering region in the contrast enhancement layer 810 can be a multi-layer structure that effectuates a band-pass interference filter with a desired transmission band. Various designs and techniques may be used for designing and constructing such filters. U.S. Patent No. 5,587,818 entitled "Three color LCD with a black matrix and red and/or blue filters on one substrate and with green filters and red and/or blue filters on the opposite substrate," and U.S. Patent No. 5,684,552 entitled "Color liquid crystal display having a color filter composed of multilayer thin films" describe examples of red, green and blue filters that may be used in the layer 810 in the screen 800 in FIG. 8.

[0087] In operation, the excitation light 120 (e.g., UV light) enters the phosphor layer 820 to excite different phosphors to emit visible light of different colors. The emitted visible light transmits through the contrast enhancement layer 810 to reach the viewer. The ambient light 801 incident to the screen 800 enters the contrast enhancement layer 810 and a portion of the incident ambient light 801 is reflected towards the viewer by passing through the contrast enhancement layer 810 for the second time. Therefore, the total optical output 802 towards the viewer includes image-carrying colored visible light emitted by the phosphor layer 820 and the reflected ambient light. This reflected ambient

light does not carry image and thus tends to wash out the image produced at the phosphor layer 820. Because this reflected ambient light towards the viewer has passed the contrast enhancement layer 810 twice and thus has been
5 filtered and attenuated twice, the intensity of the reflected ambient light is reduced by approximately two thirds of that of the received ambient light. As an example, the green and blue portions of the incident ambient light 801 comprise approximately two thirds of the flux of the ambient light 801
10 entering a red subpixel. The green and blue portions of the incident ambient light 801 are blocked by the contrast enhancement layer 810. Only the red portion of the ambient light within the transmission band of the red filter material in the contrast enhancement layer 810 transmits through the
15 layer 810 and a part of the transmitted red ambient light is reflected back to the viewer. This part of the reflected ambient light is essentially the same color for the subpixel generated by the underlying color phosphor stripe and thus the color contrast is not adversely affected.

20 **[0088]** In FIG. 8, two adjacent filter stripes in the contrast enhancement layer 810 can be separated by a stripe divider 830 made of either an optical reflective and opaque material or an optical absorbent material. Reflective dividers 830, like other stripe dividers described in this
25 application, can be used to maximize the light output of the screen. For example, reflective white materials such as barium sulfate or TiO₂ pigments can be used to form the stripe dividers 830. Other lambertian white materials may also be used to form the stripe dividers 830. The side walls of the
30 stripe dividers may be a metallized reflective layer. One way to achieve a highly efficient reflective layer that is thin for the stripe dividers 830 is to coat a sidewall with a metallized underlayer and to further place a white pigment filled layer over the metallized underlayer. Absorbing
35 dividers 830 can be used to provide color isolation and pixel

separation but the screen output efficiency may be less than that of the reflective dividers due to the loss of light by absorption of the sidewalls. In some implementations, a stripe divider 830 can include both reflective and absorbent portions. For example, a stripe divider 830 can have white reflective and opaque side walls, a white reflective facet towards the excitation side of the screen to provide optical reflection for the servo feedback, and a blackened absorbent facet towards the viewer side of the screen to reduce reflection towards the viewer and to improve the contrast.

[0089] The above use of a color-selective absorbent material in the contrast enhancement layer 810 for each subpixel to enhance the display contrast can also be implemented by mixing such a material with the light-emitting fluorescent material in each subpixel without a separate contrast enhancement layer. In one implementation, each phosphor region in the non-overlapping multi-layer design in FIG. 6 can be formed of a mixture of a fluorescent material and a color-selective absorbent material that transmits light emitted by the fluorescent material and absorbs light of other colors. Hence, the contrast enhancing feature is built into each subpixel to reduce the reflected ambient light to the viewer.

[0090] FIG. 9 shows another implementation that uses a phosphor layer 910 that uses red, green and blue phosphor materials with built-in contrast-enhancing capability for emitting red, green and blue light, respectively, in a common fluorescent layer 910 of parallel fluorescent stripes. Consider three consecutive red, green and blue phosphor stripes 911, 912 and 913. The material for the red phosphor stripe 911 is a mixture of a red phosphor emitting red light and a red ink or pigment which transmits the red light and absorbs other light including the green and blue light. Similarly, the material for the green phosphor stripe 912 is a mixture of a green phosphor emitting green light and a green

ink or pigment which transmits the green light and absorbs other light including the red and blue light; and the material for the blue phosphor stripe 913 is a mixture of a blue phosphor emitting blue light and a blue ink or pigment which
5 transmits the blue light and absorbs other light including the red and green light. This contrast-enhancing phosphor layer 910 can be combined with various screen designs and configurations described in this application.

[0091] In some implementations, the contrast enhancement
10 layer 810 in FIG. 8 can be replaced by a filter layer that blocks transmission of the excitation light and uniformly attenuates visible light at the visible colors emitted by the fluorescent layer. Hence, to the excitation light, this filter layer is opaque and prevents any excitation light to
15 appear on the viewer side of the screen; to the visible light, the filter layer behaves like a neutral density (ND) filter to attenuate the visible light including the reflected ambient light. Because ambient light that is reflected towards the viewer passes through this filter layer twice, the attenuation
20 to the reflected ambient light is twice as much as the light generated by the fluorescent layer. Therefore, the contrast of the images displayed by emitted visible light in the fluorescent screen is enhanced in comparison with the same screen without the filter layer. Such an excitation light
25 blocking ND filter layer can be less expensive than the contrast enhancement layer 810 formed of color filters. For example, this excitation light blocking ND filter layer may be a polyester layer that blocks radiation from 400 nm to 415 nm with a transmission less than 0.01% for light below 410 nm and
30 a transmission of greater than 50% for light above 430 nm. The optical attenuation of the polyester layer can be approximately uniform for visible light between 430 nm and 670 nm. The actual amount of the attenuation of this filter layer can be selected based on specific requirements for a
35 particular screen and may be above 50% in some designs and

below 50% in other designs. The optical blocking function of this filter layer may be separately implemented from the neutral density filtering function. Hence, two separated layers, one excitation light blocking layer designed to block the excitation light and another neutral density filter layer to uniformly attenuates the visible light, can be implemented on the viewer side of the fluorescent layer in the screen.

[0092] The above described fluorescent screens use different phosphor materials in different fluorescent stripes to produce different colors under excitation of the excitation light. Alternatively, different fluorescent stripes can be formed by the same fluorescent material that emits white light and can further include color filters to produce desired different colors from the fluorescent light. The contrast enhancement layer 810 in FIG. 8 can be used to implement such color filters so that each color filter achieves both contrast enhancement and generation of a designated subpixel color.

[0093] FIG. 10 illustrates an example of a fluorescent screen design that has a contiguous and uniform layer 1000 of mixed phosphors. This mixed phosphor layer 1000 is designed and constructed to emit white light under optical excitation of excitation light. The mixed phosphors in the mixed phosphor layer 1000 can be designed in various ways and a number of compositions for the mixed phosphors that emit white light are known and documented. Other non-phosphor fluorescent materials that emit white light can also be used for the layer 1000. As illustrated, a layer 810 of color filters, such as stripes of red-transmitting, green-transmitting and blue-transmitting filters, is placed on the viewer side of the mixed phosphor layer 1000 to filter the white light and to produce colored output towards the viewer. In this example, the layers 1000 and 810 are sandwiched between substrates 1001 and 1002. The color filters in the layer 810 may be implemented in various configurations, including in designs similar to the color filters used in

color LCD panels. In each color filter region e.g., a red-transmitting filter, the filter transmits the red light and absorbs light of other colors including green light and blue light. Two adjacent color filters may be separated by a divider 830 such as a reflective or absorbent separator 404.

[0094] The screen structure in FIG. 10 is simpler than other screen designs with different fluorescent stripes because the mixed phosphor layer 1000 in FIG. 10 is a contiguous layer without striped spatial structures. This construction avoids alignment issues associated with aligning the filters in layer 810 with respective fluorescent stripes in the layer 820 in FIG. 8. The substrate 1001 receives the excitation light and thus can be made of a material transparent to the excitation light, e.g., violet or UV light. The substrate 1002 faces the viewer and can be made of a material transparent to the colored light filtered by the filters in the layer 810. In fabrication, the layer 810 can be fabricated on the substrate 1002 and the layer 1000 can be fabricated on the substrate 1001. The two substrates 1001 and 1002 can be engaged to each other to form the screen. At the output surface of the second substrate 1002, an anti-reflection coating (AR) may be formed to improve the light transmission to the viewer. In addition, a hard protection layer may be formed over the second substrate 102 to protect the screen surface.

[0095] The excitation beam 120 in the above described systems can enter the fluorescent layer of the screen at a varying angle during a scan. The scanning causes the incident angle of the excitation beam 120 to the screen to change during each horizontal scan across different positions on the screen. For some screen constructions, the efficiency of the screens may be sensitive to the incident direction of the excitation beam 120 and some screen designs prefer the direction of the excitation beam 120 to be close to the normal direction to achieve a high efficiency of coupling the

excitation light into the fluorescent layer. In one implementation for controlling the incident angle of the excitation beam 120 to the fluorescent layer, an optical mechanism may be implemented at the entry to the screen, e.g., the entrance layer 411 in FIG. 4, to direct the incident excitation beam 120 to be normal or approximately normal to the screen. One example of the entrance layer 411 is a Fresnel lens layer.

[0096] FIG. 11 shows an example of a screen with a Fresnel lens layer 1110 formed at the entry side of the screen to cover the entire area of the screen that receives the excitation beam 120. The Fresnel lens layer 1110 can be formed in a dielectric substrate that may be made of, e.g., a glass or a plastic material. An acrylic plastic material, for example, may be used to form the Fresnel lens layer 1110. A dielectric layer 1112 with a different index than the Fresnel lens layer 1110 can be formed between the Fresnel lens layer 1110 and the remaining portion of the screen to create a difference in the refractive index from the Fresnel lens layer 1110 to the next layer of the screen, e.g., the first dichroic layer 412. The layer 1112 can be an air gap or a dielectric material transparent to the excitation light. The remaining portion of the screen includes the fluorescent layer 400 and other layers of the screen. A dichroic filter layer (D1) 412 on the excitation side of the fluorescent layer 400 can be implemented. In addition, an encapsulation layer 1120, a screen gain layer 423, a contrast enhancement layer 422, and a second dichroic layer D2 421 (a UV blocker) may also be provided in the screen. An anti-reflection layer 640 can be formed on the entrance surface of the Fresnel lens layer 1110 for receiving the excitation beam 120 with a minimized loss due to reflection.

[0097] In some implementations of the screen in FIG. 11, the first dichroic layer 421 (D1) can be designed to transmit light from 405 nm to 410 nm with a transmission of about

99.75% and to reflect visible light from 440 nm to 410 nm with a reflectivity of about 95%; the anti-reflection layer 640 can be designed to transmit UV light at 405 nm with a transmission of about 99.75%. The screen gain layer 423 can be designed to optically enhance the brightness and enlarge the viewing angle of the screen and may include a lenticular layer with lens elements, a diffractive optic layer of diffractive elements, a holographic layer with holographic elements, or a combination of these and other structures. The contrast enhancing layer 422 can include a color-selective absorbing pigment or dye supported in a base medium or matrix in each subpixel to absorb ambient light and to transmit light in the color of that subpixel. The spatial order of the encapsulation layer 1120, the screen gain layer 423, the contrast enhancement layer 422 and the UV-blocking dichroic layer 421 (D2) may vary with screen designs.

[0098] FIG. 12 illustrates the operation of the Fresnel lens layer 1110 in FIG. 11. The Fresnel lens layer 1110 has Fresnel rings and can be configured to redirect the incident scanning excitation beam 120 via optical diffraction, refraction or both as the incident excitation beam 1210 that is approximately normal to the screen. The Fresnel lens layer 1110 can be in a telecentric configuration for the incident scanning excitation beam 120.

[0099] The above Fresnel lens layer 1110 controls the incident direction of the excitation beam 120 into the remaining portion 1220 of the screen. Once the excitation beam 120 enters the screen, the excitation light should be fully utilized to excite the fluorescent layer and to generate visible light for displaying images to the viewer. Inside the screen, a portion of the excitation light can be redirected back towards the excitation side of the screen due to scattering and reflection by various surfaces and other screen structures within the screen. Such scattered and reflected excitation light should be recycled by directing it back to

the fluorescent layer. In addition, a portion of the emitted visible light from the fluorescent layer can also propagate towards the excitation side of the screen and would cause loss of the image brightness if not being redirected to the viewer.

5 **[00100]** The entrance layer 411 in FIG. 4 can include a prismatic layer to reflect backward propagating excitation light and visible light, that propagates towards the entrance layer from the fluorescent layer, back to the fluorescent layer. Such a prismatic layer has parallel periodic prism
10 stripes with apexes of a predetermined apex angle (e.g., 90 degrees) to form angled facets to direct the received excitation beam 120 into the screen by refraction. Each apex has two opposing angled facets that refract and reflect light and hence parallel rays in a common incident direction are
15 refracted or reflected into two groups of parallel rays into two directions away from each other. The prismatic layer reflects light in various directions propagating from the fluorescent layer of the screen towards the prismatic layer back to the fluorescent layer by reflection at the angled
20 facets including the total internal reflection for rays at incident angles into the angled facets greater than the critical angle for the total internal reflection angle. The reflected excitation light is recycled back to the fluorescent layer to further excite the fluorescent layer and thus the
25 utilization of the excitation light for generating the visible fluorescent light is enhanced. In addition, the fluorescent light propagating towards the prismatic layer is also reflected towards the fluorescent layer and the viewer to enhance the brightness of the screen perceived by the viewer.

30 **[00101]** FIG. 13 shows one implementation of a fluorescent screen having a prismatic layer 1310 and an adjacent screen layer 1320 within the screen. The screen layer 1320 can be a fluorescent layer as shown and can be another layer on the excitation side of the fluorescent layer. The prismatic layer
35 1310 includes an array of prism elements 1311, e.g., an array

of prism stripes having angled facets 1312 with an apex angle at 90 degrees. The angled facets 1312 are used to receive the excitation light 120. The width of each prism stripe can be greater than the wavelength of the excitation light and can be less than the width of each fluorescent stripe, i.e., the width of one subpixel of the screen. A cross sectional view is shown in FIG. 13 where the parallel prism stripes are perpendicular to the cross section.

[00102] The prismatic layer 1310 can be aligned to place the prism stripes parallel to the fluorescent stripes in the fluorescent layer 1320 in a parallel configuration or perpendicular to the fluorescent stripes in a cross configuration. In each prism stripe, the two angled facets 1312, which intersect with each other at the prism apex 1313, refract or reflect light parallel rays into two groups of parallel rays into two different directions in a plane perpendicular to the prism stripes. In the cross configuration, the two split beams that are split from the excitation beam 120 are directed to two locations within the same fluorescent stripe and hence does not cause spatial spreading of the excitation light along a direction perpendicular to the fluorescent stripes. As a result, the cross configuration can be used to prevent light of the excitation beam 120 from entering two adjacent fluorescent stripes at the same time. Recall that the excitation beam 120 is turned on to illuminate one fluorescent stripe to address one subpixel at a time. When a portion of an optical pulse in the excitation beam 120 intended to address one fluorescent stripe is split by the prism stripe and is directed to an adjacent fluorescent stripe, a cross talk between two adjacent subpixel occurs and can lead to degradation in color purity and image resolution. This can occur when the prismatic layer 1310 is in the parallel configuration where the splitting of the excitation beam 120 by each prism stripe is along the direction perpendicular to the fluorescent stripes. In the

parallel configuration, the visible fluorescent light generated in one fluorescent stripe that propagates towards the prismatic layer 1310 can also have a higher probability of being reflected by the angled prim facets into an adjacent
5 fluorescent stripe.

[00103] FIG. 13A shows operation of a prism stripe 1311 of the prismatic layer 1310 in coupling the excitation beam 120 into the screen. The two angled facets 1312 are separated identified as facets 1312A and 1312B which interest at the
10 apex 1313. In the xyz coordinate shown, the prism stripe is placed to be parallel to the y direction. The excitation beam 120, shown in a normal incidence to the prismatic layer 1310, is split by the facets 1312A and 1312B as two beams 120A and 120B, respectively. The two beams in the two different
15 directions arrive the fluorescent layer 400 at two different locations x1 and x2 along the x direction. This feature of the prism stripe creates double imaging. Hence, in the cross configuration where the prism stripes are along the y direction and the fluorescent stripes in the fluorescent layer
20 400 are in the x direction, the locations x1 and x2 are two different locations along the longitudinal direction of the fluorescent stripe and thus are the same fluorescent stripe. In the parallel configuration where the prism stripes and the fluorescent stripes are parallel and are all along the y
25 direction, the two locations x1 and x2 are separated from each other along the direction perpendicular to the longitudinal direction of a fluorescent stripe and thus can fall in two adjacent fluorescent stripes. The amount of the separation between the two beams 120A and 120B at the fluorescent layer
30 400 depends on the thickness of the prismatic layer 1310 and the distance between the fluorescent layer 200 and the prismatic layer 1310. Both alignment configurations for the prismatic layer 1310 can be used and the cross configuration may be preferred in some screen designs. In either
35 configuration, the thickness of the prismatic layer can be

minimized to minimize the effect of the double imaging of the prism stripe on the fluorescent layer.

[00104] The prismatic layer 1310 can be formed in a dielectric layer that is transparent to the excitation light 120 and has a refractive index n_2 greater than the refractive index n_1 of the transparent material above the angled facets 1312. The material above the angled facets 1312 can be air or a low-index transparent material. The material for the prismatic layer 1310 is selected to have a large refractive index n_2 so that a small critical angle $\theta_{cr} = \arcsin(n_1/n_2)$ for the total internal reflection (TIR) is achieved at the angled facets 1312. The angled facets 1312 is used to receive the excitation light 120.

[00105] Depending on the screen designs, the screen layer next to the prismatic layer 1310 can be selected from various layers, e.g., an air gap, a low index layer with a lower refractive index than that of the prismatic layer, or a high index layer with a higher refractive index than that of the prismatic layer. In the specific example illustrated in Fig. 13, behind the prismatic layer 1310 is a layer 1320 that has a refractive index n_3 that is approximately equal to the refractive index of the prismatic layer 1310. The index matching condition reduces undesired optical reflection at the interface between the prismatic layer 1310 and the layer 1320 and thus reduces the optical loss of the excitation light 120. The layer 1320 can be a dielectric layer that is transparent to excitation light 120 and is located between the prismatic layer 1310 and the fluorescent layer of the screen. The layer 1320 can also be the fluorescent layer which is formed by a layer of a binder material in which the fluorescent particles are embedded.

[00106] In operation, the scanning excitation light 120 is refracted by the angled facets when entering the prismatic layer 1310 and the refracted excitation light enters the screen to excite the fluorescent layer which generates visible

fluorescent light to display images. A portion of the
excitation light that is not absorbed and a portion of the
fluorescent light can propagate towards the prismatic layer
1310. Although such light in all angles is reflected by the
5 angled facets, a portion of such light can be totally
reflected back into the screen at the angled facets by the
total internal reflection (TIR) for rays with incident angles
greater than the TIR critical angle. The reflected excitation
light is thus recycled by interacting with the phosphor layer
10 again and causing the phosphor to radiate the fluorescent
light. The reflected fluorescent light is scattered by the
phosphor, a portion of which exits from the viewing side.
Thus, the prismatic layer 1310 improves utilization of the
excitation light and enhances the brightness on the viewing
15 side of the phosphor screen.

[00107] Notably, the prism apex angle and the index of the
prismatic layer 1310 can be selected so that backward
propagating light rays at or near the normal incidence to the
screen have incident angles at each angled facet 1312 that are
20 at or greater than the TIR critical angle for that angled
facet 1312. Light ray 1341 as shown is one example of such a
ray and is totally reflected at a respect angled facet 1312.
The normal direction for each angled facet 1312 is different
from the normal direction of the screen and forms an angle
25 with the normal direction of the screen by one half of the
prism apex angle. Light ray 1342 as shown is incident to an
angled facet 1312 at an angle around one half of the prism
apex angle with respect to the normal direction of the screen
plane and thus is near the normal incidence for that angled
30 facet 1312. This light ray 1342 thus is partially reflected
and the rest of the light transmits through the prismatic
layer. The transmitted portion of the light ray 1342 is lost
and represents the loss for the screen. As a result, the
prismatic layer 1310 can totally reflect backward propagating
35 light rays incident at a wide range of angles, including light

rays at the normal incidence to the screen and large angles. Light rays incident to the prismatic layer 1310 around the one half of the prism apex angle, however, are not totally reflected and are only partially reflected.

5 **[00108]** The entrance layer 411 can be implemented by using a flat layer formed of a high-index material n_2 that is transparent to the excitation light 120 in lieu of the prismatic layer 1310. FIG. 14 shows an example high-index layer 1410. The substrate or rigid layer 630 in FIG. 6 is
10 also an example of such an entrance layer. The entrance surface of the layer 1410 is flat and the reflection at the entrance surface 1412 including the TIR can direct both backward propagating excitation light and the fluorescent light back into the screen to recycle the excitation light and
15 to "push" more fluorescent light to the viewer side of the screen. This function of the flat high-index layer 1410 is similar to the prismatic layer 1310. The index n_2 of the flat layer 1410 should be as high as possible to make the TIR critical angle at the entrance surface 1412 as small as
20 possible to increase the total reflection. Different from the prismatic layer 1310, the normal direction of the entrance surface 1412 is the normal direction of the screen and thus light rays incident at or near the normal incidence to the screen with incident angles less than the TIR critical angle
25 at the surface 1412 are partially reflected and partially transmitted. Light rays with incident angles with respect to the normal incidence of the screen greater than the TIR critical angle are totally reflected. In certain implementations of the prismatic layer 1310 in FIG. 13 or the
30 high-index layer 1410 in FIG. 14 as an entrance layer to the screen, the index-matched layer 1320 next to the layer 1310 or 1410 may be replaced by a low index layer with an index less than the player 1310 or 1410, such as an air gap or a low-index dielectric layer.

[00109] The above prismatic layer 1310 and the high-index layer 1410 have different TIR properties, including different angular responses in reflecting light incident at different angles. Hence, the prismatic layer 1310 in FIG. 13 and the high-index layer 1410 in FIG. 14 may be combined together on the excitation side of the fluorescent layer to increase the optical throughput of the screen. In one implementation, the prismatic layer 1310 in FIG. 13 and the high-index layer 1410 in FIG. 14 may be spaced from each other by an air gap or a low-index layer as the entrance layer for the screen. The prismatic layer 1310 reflects light at small incident angles via the total internal reflection while the high-index layer 1410 reflects light at large incident angles via the internal total reflection. For example, the layers 1310 and 1410 can be used as part of the entrance layer and are spaced from each other by a low index layer or an air gap. The prismatic layer 1310 can be the first layer to receive the excitation beam 120 which transmits through the air gap or low-index layer into the layer 1410 or the layer 1410 can be the first layer to receive the excitation beam 120 which transmits through the air gap or low-index layer into the prismatic layer 1310. The surface 1412 of the layer 1410 is designed to have an TIR critical angle that is less than the TIR critical angle for each angled facet 1312 of the prismatic layer 1310 so that light rays that are partially reflected by the prismatic layer 1310 are totally reflected by the layer 1410. Under this configuration, the light rays at or near the formal direction of the screen that are not totally reflected by the layer 1410 are totally reflected by the prismatic layer 1310. Therefore, this combination of the layers 1310 and 1410 effectuates the function of the dichroic layer (D1) 412. The dichroic layer (D1) 412, when implemented by a multilayer structure as an interference filter, may be sensitive to incident angles where the dichroic function can be performed to light rays at or near the normal incidence or within a limited angular range

for the incidence angles. The above combination of layers 1310 and 1410 is not sensitive to the incident angles and reflect backward propagating light at all angles. In addition, the spectral properties of a multilayer interference
5 dichroic filter can be limited and can vary with the incident angles of the beams. The above combination of layers 1310 and 1410 is essentially free of such performance limitations of the a multilayer interference dichroic filter.

[00110] Fluorescent screens can be designed to combine the
10 second dichroic layer 421 (D2) on the other side of the fluorescent layer, the prismatic layer 1310 or the high-index layer 1410 and the second dichroic layer 421 (D2) to confine a significant amount of the excitation light to bounce back and forth through the fluorescent layer between the prismatic
15 layer 1310 (or the high-index layer 1410) and the second dichroic layer 421 (D2) to improve the utilization of the excitation light and the amount of generated fluorescent light.

[00111] The following sections now describe some specific
20 fluorescent screen designs that implement selected screen elements described above.

[00112] FIG. 15 shows a multilayered fluorescent screen that implements a prismatic layer 1310 to couple excitation light into a fluorescent layer 1570. The screen includes a
25 transparent substrate 1510 that faces the viewer side and transmits the colored light carrying images to the viewer. An array of opaque subpixel stripe dividers 1520 are formed on one surface of the transparent substrate 1510 to define the fluorescent stripes and optically separate adjacent or
30 neighboring fluorescent stripes (i.e., adjacent subpixels). The stripe dividers 1520 may be made of a solid opaque film resist, an ink material printed on the substrate 1510, or an optical reflective or absorbent material. Between the stripe dividers 1520 are contrast enhancement color filters 1530
35 shaped as parallel stripes where three adjacent filers

transmit three different designated colors, respectively, and absorb light of other colors different from their designated colors. Three adjacent filters 1531, 1532 and 1533 are examples for the filters 1530, where the filter 1531 is a red-transmitting filter that absorbs light of green and blue, the filter 1532 is a green-transmitting filter that absorbs light of red and blue, and the filter 1533 is a blue-transmitting filter that absorbs light of green and red. The operation and effect of the filters 1530 in combination with the fluorescent layer 1570 having fluorescent stripes emitting different fluorescent colors are described with reference to FIG. 8.

[00113] The screen in FIG. 15 includes a dielectric layer 1540 formed above and are supported by stripe dividers 1520 and below the fluorescent layer 1570. The dielectric layer 1540 and the filters 1530 are spaced apart by a low-index layer or an air gap 1550 which has an index less than that of the dielectric layer 1540. The height of the stripe dividers 1520 can be used to control the thickness of the low-index layer or the air gap 1550 which may be 10 to 50 microns. In some implementations, the dielectric layer 1540 can be a transparent material with a refractive index less than that of the fluorescent layer 1570 such as a clear PET plastic layer of about 50 microns. In other implementations, the dielectric layer 1540 can be a dichroic layer (D2) that transmits visible light and reflects the excitation light at a UV or violet wavelength. may be formed on top of the array of the stripe dividers and below the fluorescent layer.

[00114] The fluorescent layer 1570 in FIG. 15 can be repetitive different parallel fluorescent stripes for emitting different fluorescent colors (e.g., red, green and blue) and is formed over the layer 1540. Spatially corresponding to the opaque subpixel stripe dividers 1520, a second array of stripe dividers 1560 are formed on the layer 1540 to physically separate different fluorescent stripes 1570 so that each of

the fluorescent stripe 1570 is aligned with a respective filter 1530.

[00115] The stripe dividers 1560 can be made from an optical reflective or diffusive material to direct at least part of the incident excitation light 120 as feedback light back to the excitation side of the screen to be received by one or more servo photodetectors for a servo control of the display system. The power of the reflected excitation light produced by the stripe dividers 1560 varies with the position of the beam on a fluorescent stripe and thus can be used to determine a relative position of the excitation beam 120 on the fluorescent stripe and can be used to control the optical alignment between the excitation beam 120 and respective fluorescent stripes during a horizontal scan. In this context, the stripe dividers 1560 function as servo marks and are reflective at least at their facets facing the excitation side of the screen. The stripe dividers 1560 can also be made to include an IR-emitting fluorescent material or other fluorescent material emitting light at a wavelength different from the excitation light 120 and the visible light emitted by the fluorescent layer 1570 that is excited by the same excitation laser light 120 for the fluorescent layer 1570. Such fluorescent stripe dividers 1560 can be used to improve the detection signal to noise ratio at the one or more servo photodetectors because scattered excitation light and the visible fluorescent light generated by the fluorescent layer 1570 can be filtered out to allow only the IR light to be detected by the one or more servo photodetectors for the servo control operation. Details of the stripe dividers 1560 as servo stripe marks and the servo control are described in PCT Application No. PCT/US2007/004004 entitled "Servo-Assisted Scanning Beam Display Systems Using Fluorescent Screens" and filed on February 15, 2007 (published as PCT Publication No. _____), which is incorporated by reference as part of the specification of this application.

[00116] On top of the fluorescent layer 1570 in FIG. 56, the prismatic layer 1310 is formed to transmit the excitation laser light in the UV or violet range and to reflect light, both the excitation light and the fluorescent light, from the fluorescent layer 1570. Hence, the prismatic layer 1310 effectuates the function of the dichroic layer 412 (D1) described above for reducing loss of the fluorescent light to the excitation side of the screen. In addition, the prismatic layer 1310 also recycles the unabsorbed excitation light back to the fluorescent layer 1570.

[00117] Notably, between the prismatic layer 1310 and the fluorescent layer 1570, a low index transparent layer 1580 with an index less than that of the fluorescent layer 1570 is formed to increase the optical throughput of the screen. A polymer material or an air gap can be used as the second low index transparent layer 1580. Referring to preceding description for the prismatic layer 1310 in FIG. 13 and the flat high-index layer 1410 in FIG. 14, the layers 1310 and 1410 can be combined to effectuate total internal reflection to backward propagating rays at all angles. In FIG. 15, the fluorescent layer 1570 effectively provide the function of the high-index layer 1410 in FIG. 14. Backward propagating light rays at incident angles to the interface between the layers 1570 and 1580 greater than the TIR critical angle at this interface are totally reflected, including both the excitation light and the fluorescent light generated in the layer 1570. Backward propagating light rays with incident angles less than the TIR critical angle at this interface are partially reflected by the interface and partially transmit through the layer 1580 to enter the prismatic layer 1310. This portion of the backward propagating light is then totally reflected by the angles facets 1312 of the prismatic layer 1310.

[00118] FIG. 16 illustrates another screen based on the design in FIG. 15 where a fluorescent layer 1610 of identical parallel stripes made of a single mixture of different

phosphors that emits white light is used to replace the fluorescent layer 1570 with fluorescent stripes made of different fluorescent materials. The color generation is achieved by using the color filters 1530 based on the design
5 in FIG. 10.

[00119] FIG. 17 shows another example of a screen design with the prismatic layer 1310 where a single array of stripe dividers 1710 are used to separate both the parallel stripe color filters 1530 and parallel fluorescent stripes 1720 made
10 of a single white-light-emitting fluorescent material or different fluorescent materials emitting different colors. The separate array of stripe dividers 1560 as servo marks in the designs in FIGS. 15 and 16 is eliminated to simplify the screen structure. The single array of stripe dividers 1710 is
15 used as both stripe dividers and the servo marks and can be made of a material for the stripe dividers 1560. Different from the designs in FIGS. 15 and 16, this example uses a low index transparent layer 1730 formed between and in direct contact with each color filter 1530 and the fluorescent layer
20 1720. The low index transparent layer 1730 has a refractive index less than that of the fluorescent material to increase the optical throughput into each color filter 1530 of the screen with reduced optical loss caused by the total internal reflection at their interface. The layer 1730 may a gel layer
25 that is sealed between the layers 1720 and 1730. A second low index transparent layer 1580 with an index less than that of the prismatic layer 1310 and the fluorescent material is formed between the prismatic layer 1310 and the fluorescent layer 1720 to increase the optical throughput of the screen.
30 A polymer material or an air gap can be used as the second low index transparent layer 1580.

[00120] FIGS. 18 and 19 show two exemplary screens that use the high-index flat layer 1410 in FIG. 14 as the entrance layer for the screen. In FIG. 3B, the screen is based on the
35 screen structures in FIGS. 15 and 16 and uses the high index

layer 1410 to replace the prismatic layer 1310 and the low index layer 1580. In FIG. 19, the screen is based on the screen structure in FIG. 17 and uses the high index layer 1410 to replace the prismatic layer 1310 and the low index layer
5 1580. layer.

[00121] FIG. 20 shows a fluorescent screen design where the dichroic layers 412 (D1) and 421 (D2) are formed on two sides of the fluorescent layer 1720 based on the design in FIG. 4. A low index transparent layer 2010 is formed between the
10 dichroic layer 421 and the substrate 1510 to improve the optical throughput to the viewer. An array of stripe dividers 1560 are formed to separate adjacent fluorescent stripes and to also operate as the servo marks for the above servo feedback control as described in FIG. 15.

[00122] FIG. 21 shows a screen design based on the design in FIG. 17. A dichroic layers 412 (D1) that transmits the excitation light 120 and reflects fluorescent light emitted by the fluorescent layer 1720 is used to replace the prismatic layer 1310. Parallel fluorescent stripes 1720 can be made of
20 a single white-light-emitting fluorescent material or different fluorescent materials emitting different colors. The stripe dividers 1710 are used to both physically separate adjacent fluorescent stripes and operate as servo marks for the above servo feedback control as described with reference
25 to FIG. 15.

[00123] FIG. 22 shows another screen design based on the design in FIG. 14. A rigid support substrate 2230, such as a transparent plastic or glass material, is used as a base to support various screen layers with a planar screen stack 2210.
30 An optical grad acrylic substrate, for example, can be used to form the substrate 2230. The planar screen stack 2210 includes a film base layer 2202 which operates as the high-index layer 1410 shown in FIG. 14 to couple light into the screen and to reflect light back into the screen based on
35 total internal reflection. A polyester film, such as the

commercially available DuPont Teijin film and Mylar DL film, can be used as the layer 2202. A filter support layer 2201, such as a protective liner, may be attached to the polyester film 2202. This support layer 2201 may be used to protect
5 film base layer 2202 during the fabrication and can be removed after the screen is fully assembled. The support layer 2201 may also be retained after the fabrication as a protection layer. A layer 1570 of fluorescent stripes is formed in contact with the film base layer 2202 and are divided by
10 stripe dividers 2203. The dividers 2203 are optically reflective at its facets or sidewalls in contact with the film base layer 2202 and the fluorescent stripes in the fluorescent layer 1570. A dielectric layer 1540 is formed above the stripe dividers 2203 and to form a space between the layer
15 1540 and the fluorescent layer 1570. This space can be an air gap or be filled with a low index layer 1730 with a refractive index less than that of the fluorescent regions in the fluorescent layer 1570. A contrast enhancement layer 1530 with different color filters is formed on the layer 1540. An
20 adhesive layer 2220, e.g., an optically clear laminating adhesive, is used to adhere the planar screen stack 2210 to the substrate 2230. At the exit surface of the substrate 2230 that faces the viewer, an anti-reflection layer 2240 can be formed to reduce the glare of the screen due to reflection of
25 ambient light.

[00124] FIG. 23 shows details of the stripe dividers 2203 according to one implementation. All dimensions are in microns and are exemplary. The body of each divider 2202 is optically reflective and can be made of an optical reflective
30 material. As an option, the divider facet that faces the viewer side of the screen can be coated with a blackened absorptive layer 2310 to reduce any reflection towards the viewer side, e.g., less than 10% in reflection and greater than 80% in absorption from 400 nm to 650 nm. This feature
35 can enhance the resolution and contrast of the screen.

Various optically reflective materials can be used to form the dividers 2203. Metal materials such as aluminum can be used to construct the dividers 2203 or as coating materials to form a coating on a surface or facet of each divider that needs to be reflective. In addition, a white paint material can also be used to form the dividers 2203 to achieve a high reflectivity. For example, a white paint made of a TiO₂-filled resin or a barium sulfate-filled resin can be formulated to achieve superior reflective properties to metal coatings, especially when reflecting back into a clear polymer. The reflectivity of the white paint material can be greater than 90% from 400 nm to 650 nm.

[00125] Furthermore, the stripe dividers 2203 can also be made to include an IR-emitting fluorescent material or a fluorescent material emitting light at a wavelength different from the excitation light 120 and the visible light emitted by the fluorescent layer 1570 that is excited by the same excitation laser light 120 for the fluorescent layer 1570. Such fluorescent stripe dividers 2203 can be used to improve the detection signal to noise ratio at the one or more servo photodetectors because scattered excitation light and the visible fluorescent light generated by the fluorescent layer 1570 can be filtered out to allow only the IR light to be detected by the one or more servo photodetectors for the servo control operation. The facet on each divider 2203 facing the viewer side can be coated with the absorptive layer 2310.

[00126] FIGS. 24 and 25 show two example screen designs that replace a color filter based contrast enhancement layer with a filter layer that blocks the excitation light and uniformly attenuates visible light to enhance the display contrast. In FIG. 24, a planar screen stack 2410 replaces the stack 2210 in FIG. 22. The stack 2410 includes a filter layer 2413 which blocks excitation light (e.g., light between 400 nm and 415 nm) from transmitting to the viewer side and uniformly attenuates the visible light, e.g., from 430 nm to 670 nm, as

an ND filter. A polyester film can be used as the filter layer 2413. Two optically clear laminating adhesive layers 2411 and 2412 are used to engage the filter layer 2412 to the stripe dividers 2203 on one side and to the substrate 2230 on the other side.

[00127] In FIG. 25, a rigid support substrate 2520 is used to provide the excitation blocking function and the ND filtering function of the filter layer 2413 in FIG. 24, thus eliminating the filter layer 2413. This simplifies the screen construction. The planar screen stack 2510 in this example includes a laminating adhesive layer 2511, the stripe dividers 2203, the fluorescent layer with fluorescent stripes 1570, the low index layer 1730 between the fluorescent layer and the laminating adhesive layer 2511 and the high-index film base layer 2202.

[00128] In some of the screen designs, one or more layers may be a contiguous layer across the fluorescent stripes without being divided into stripes by the stripe dividers. For example, the film base layer 2202 in FIGS. 22, 24 and 25, and the dielectric layer 1540 in FIGS. 15, 16, 18 and 22, the capsulation layer 1120, the gain layer 423 in FIGS. 4 and 11 and the high-index layer 1401 in FIGS. 14, 18, 22, 23, 24 and 25 are such a contiguous layer. In such a contiguous layer, emitted visible light from the fluorescent light can be reflected back and forth at the two surfaces of the contiguous layer and thus may be reflected into an adjacent subpixel to cause smear of images. In addition, excitation light targeted at one subpixel may also be reflected into an adjacent subpixel to excite a wrong color at the adjacent subpixel to cause a undesired halo effect. One way to reduce these adverse effects is to limit the thickness of such a contiguous layer to a value less than a width of a subpixel, e.g., 10 times less than the width of a subpixel along the horizontal direction that is perpendicular to the fluorescent stripes.

[00129] In the above screen designs, the colored fluorescent light emitted from the phosphor layer passes through various interfaces between two different layers or materials in the path towards the viewer. At each of such interfaces, a difference in the refractive indices at the two sides of the interface causes undesired reflection. In particular, the total internal reflection can occur at an interface when the emitted colored light propagates from a layer with an index higher than the next layer when the incident angle is greater than the critical angle of that interface. Therefore, in some implementations, the optical materials may be selected to have refractive indices as close as possible to minimize the reflection. In other implementations, a difference in refractive indices at an interface is intentionally created to achieve certain effects.

[00130] For example, the fluorescent layer in some of the fluorescent designs can have an adjacent low-index dielectric layer with a low refractive index on the viewer side of the fluorescent layer. The refractive index of the low-index dielectric layer is less than the index of the fluorescent layer and the index of another screen layer that is in contact with the low-index dielectric layer. FIG. 26 illustrates an example of this structure as part of a fluorescent screen. This example shows only a part of the screen to illustrate three consecutive screen layers of this structure: a fluorescent layer 2600, a low-index dielectric layer 2610 and a screen layer 2620 as the viewer-side outer layer of the screen. Fluorescent light emitted in the fluorescent layer 2600 can transmit through the low-index dielectric layer 2610 and the screen layer 2610 to exit the screen and to reach the viewer. The structure in FIG. 26 can use the low-index dielectric layer 2610 to increase the throughput of the fluorescent light from the fluorescent layer 2600 to the viewer side of the screen and to reduce cross talk between two adjacent fluorescent stripes in the fluorescent layer 2600

caused by reflection of the fluorescent light on the viewer side of the fluorescent layer 2600.

[00131] In this design, most of the fluorescent light propagating inside the fluorescent layer 2600 towards the layer 2610 partially transmits and is partially reflected at the interface 2601 between the layers 2600 and 2610. Because the index of the low-index dielectric layer 2610 is less than the fluorescent layer 2600, a portion of the fluorescent light that arrives at the interface an angle greater than the critical angle for the total internal reflection (TIR) is completely reflected back to the fluorescent layer 2600. Hence, the TIR condition creates an angular filtering function at the interface 2601 to allow transmission of fluorescent light with small incident angles less than that of the TIR critical angle and to block transmission of fluorescent light with larger incident angles. At the interface 2611 between the layers 2610 and 2620, there is no total internal reflection towards the layer 2610 because the index of the layer 2610 is less than that of the layer 2620. The fluorescent light at all angles partially transmits through the interface 2611 to enter the layer 2620 and is partially reflected back to the layer 2610. Because the TIR condition at the interface 2601 limits the angles of the fluorescent light entering the layer 2610 to be less than the TIR critical angle at the interface 2601, a fluorescent light ray 2632 in the layer 2620 that is the transmission of the light ray 2631 in the layer 2631 also has a maximum angle determined by the indices of the layers 2600, 2610 and 2620. The layer 2620 has an exit surface 2621 that is also the screen surface to interface the air. Accordingly, a total internal reflection can occur to light in the layer 2620 with an incident angle greater than the TIR critical angle at the interface 2621.

[00132] The TIR at the interface 2621, however, reduces the amount of fluorescent light that exits the screen towards the viewer. This reduces the screen brightness. In addition, the

reflected light by the TIR at the interface 2621 may cause fluorescent light in one color generated by one fluorescent stripe to enter an adjacent fluorescent stripe of a different color and thus lead to cross talk between two adjacent
5 fluorescent stripes. For example, the blue light from a blue fluorescent stripe can excite the red and green fluorescent stripes to emit light. When this cross talk occurs, a blue spot on the screen can cause glowing in adjacent red and green pixels, often known as an image halo. As a result, this TIR
10 at the interface 2621 can cause degradation in color purity and the image resolution.

[00133] In recognition of at least the above, the indices of the layers 2600, 2610 and 2620 can be selected so that a fluorescent light ray 2630 in the fluorescent layer 2600 that
15 originates the light ray 2631 in the layer 2610 and the light ray 2632 in the layer 2620, when at an incident angle equal to the TIR critical angle at the interface 2601, leads to the incident angle of the light ray 2632 at the exit surface 2621 of the layer 2620 to be no greater than the TIR critical angle
20 at the interface 2621. Under this condition, the fluorescent light that transmits through the interface 2601 from the fluorescent layer 2600 into the low-index layer 2610 will not be totally reflected at the interface 2621. Notably, the low-index layer 2610 can be an air gap which has the lowest index
25 or a dielectric material with a desired low index. This feature has been shown in some of the examples described above, including screens in FIG. 15, 16, 18, 22, 24 and 25.

[00134] As discussed above, the feedback light generated by servo reference marks in the fluorescent area of the screen
30 can be used for detecting the location of the scanning beam 120 relative to the center of an individual subpixel on the screen. The periodic structure of the fluorescent stripes or periodic features formed on the periodic structures of the fluorescent stripes can be used as servo reference marks which
35 scatter or reflect a portion of the scanning excitation beam

120 and the scattered or reflected light from such servo reference marks is detected to measure the presence of the misalignment and the direction of the misalignment. Strip dividers between fluorescent or phosphor stripes can be made
5 optically reflective to the excitation light and thus produce the feedback light for the servo control over the alignment of optical pulses of the excitation light and individual subpixels.

[00135] FIG. 27 illustrates one example of a fluorescent screen
10 having optically reflective stripe dividers that provide servo feedback light. In this example, the screen includes a support substrate layer 3760 to support other screen layers and components. The fluorescent layer as shown includes parallel and spaced strip dividers 3730 and fluorescent
15 stripes 3740 between the strip dividers 3730. Adjacent fluorescent stripes 3740 are made of different materials that emit light of different colors, e.g., red (Red), green (G) and blue (B) in three consecutive stripes. An air gap 3750 or a low-index dielectric layer can be formed between each
20 fluorescent strip 3740 and the support substrate layer 3760 to enhance transmission of emitted visible light from a fluorescent stripe 3740 to the viewer through the support substrate layer 3760. A dielectric layer 3720 is formed over the fluorescent stripes 3740 and may be configured to transmit
25 the excitation light 120 while reflecting emitted visible light by the fluorescent stripes 740 (e.g., a dichroic material). Because the support substrate layer 3760 is positioned on the viewer side of the fluorescent stripes 3740, the support substrate layer 3760 can be made of a material
30 transparent or partially transparent to the visible colored light emitted by the fluorescent stripes 3740. A partial transparent material having a uniform attenuation to the visible light including the three colors emitted by the fluorescent stripes can be used in the support substrate layer
35 3760 to operate like an optical neutral density (ND) filter.

In addition, the support substrate layer 3760 may be made reflective and opaque to the excitation light of the excitation beam 120 to block the excitation light from reaching the viewer and to recycle the unabsorbed excitation light back to the fluorescent stripes 3740.

[00136] The excitation light 120 is directed to the screen through a scan lens 360 and at least one servo optical detector 3710 is provided to detect the reflected excitation light as feedback light primarily by the stripe dividers 3730. Two servo optical detectors 3710 are shown to be located near the scan lens 360 in the example in FIG. 27. One or more servo detectors can be placed on other locations to receive the feedback light, e.g., near the screen 101.

[00137] FIG. 28 illustrates one example of reflective stripe dividers for various screen designs in this application including the designs in FIGS. 23 and 27. Each reflective stripe divider 3730 is made of a mixture of beads 3821 and a bead binder material 3822 where the bead binder material 3822 provides a matrix in which the beads 3821 are distributed and supported. The beads 3821 can be made of a dielectric material with a refractive index greater than the refractive index of the bead binder material 3822 to effectuate optical reflection. For example, the beads 3821 may be made of a glass or other transparent material with an index of 2.0 or greater and the bead binder material 3822 is made of a resin or other material with an index of 1.5. The beads 3821 can be in various sizes, e.g., from several microns to tens of microns, or hundreds of microns. A 10-micron glass bead, for example, can be used as the beads 3821.

[00138] In operation, each bead 3821 effectuates an optical reflector to reflect at least a portion of the excitation light 120 that enters the bead 3821. Because the refractive index of the bead binder material 3922 is less than that of the beads 3821, the excitation light incident to a bead 3821 from the bead binder material 3822 is at least partially

refracted at the binder-bead interface to enter the bead 3821 without the total internal reflection. At least a portion of the excitation light inside the bead 3821 is reflected back as the feedback light 3770. The mixture of beads 3821 and a bead
5 binder material 3822 should also be opaque to light in order to optically isolate two adjacent fluorescent stripes 3740 to avoid cross talk that would otherwise degrade the image quality of the display. The degree of the opaqueness can vary depending on the requirement on the tolerance for the cross
10 talk in the display.

[00139] The properties of being both optically reflective and optically opaque of the mixture of beads 3821 and a bead binder material 3822 can be achieved by various designs of the mixture. FIGS. 29A and 29B illustrate two examples of bead
15 designs for the beads 3821 used in the stripe dividers 3720 in FIG. 28.

[00140] FIG. 29A shows a bead 3910 that is coated with a layer 3920 of partially transmissive and partially reflective coating over the entire exterior surface. The partial
20 transmission of the coated layer 3920 permits entry of excitation light 120 and export of light and the partial reflection of the coated layer 3920 allows reflection of light either inside the bead 3910 or outside the bead 2910 at the interface with the bead binder material 3822. Such coated
25 beads can be used to produce the desired reflection for producing the feedback light 3770 and to produce a desired degree of opaqueness of the stripe dividers 3730. As an example, a transparent glass, plastic or polymer bead can be coated with a semi-transmissive metal layer as the coated
30 layer 3920.

[00141] FIG. 29B shows a bead 3910 which has a portion of the exterior surface coated with a reflective coating 3930 while leaving the rest of the exterior surface exposed. For
example, one hemisphere of each bead 3910 can be coated with a
35 reflective coating 3930. In one implementation, the

reflective coating 3930 can be a totally reflective metal coating. When such partially coated beads are mixed in a suitable bead binder material such as a resin, the beads can be oriented in all directions relative to each other. Hence,
5 in a stripe divider 3730 made of such a mixture, some beads may be in an "ideal" orientation where the uncoated part of the beads faces the excitation side of the screen to receive the excitation light and to reflect back the received excitation light while other beads may be in other
10 orientations with some beads with their coated part of the beads facing the excitation side of the screen. The random nature of the bead orientation insures that at least a portion of light will be retro-reflected and a portion of light that is not retro-reflected will be blocked from penetrating
15 through the mixture, thus providing a desired level of opaqueness in each strip divider.

[00142] Materials of the beads and the binder material can be selected to optimize the retro-reflection of each bead. Referring to FIG. 29B, the focal distance f of the spherical
20 inner surface of the bead placed in air is $1/f = (n_{\text{bead}} - 1)/2r$, where n_{bead} is the refractive index of the bead. Hence, when the index of the bead is 2, the focal length is $2r$ where the reflected beam 3770 caused by a single reflection at the inner surface of the bead 3910 is parallel to the incident light
25 beam 120 as a "retro-reflected" beam.

[00143] FIG. 30 illustrates one example of reflective stripe dividers 3730 in FIG. 27 where a prism stripe is placed on top of the dielectric layer 3720 over each stripe divider 3730 to overlap with the underlying stripe divider 3730 to produce the
30 reflected feedback light. FIG. 30 shows three of such prism stripes 4010, 4020 and 4030 at three different locations of the screen: near left-hand side of the screen, at the center of the screen and near the right-hand side of the screen, respectively. Various prism designs may be used for such
35 prism stripes. In the illustrated example, each prism stripe

is a right-angled prism one side of the right angle of the prism is placed on the dielectric layer 3720. As illustrated by light rays in each of the three prisms 4010, 4020 and 4030, the reflection in each prism produces the desired reflected feedback light 4040. When right-angled prisms are used, the orientations of the prisms on the left and right hand sides of the center of the screen can be in opposite directions as shown.

[00144] Referring to FIGS. 23 and 27, a screen layer for the screen 101 can be formed with a flat panel base 2202 and stripe dividers 2203 on the base 2202 (FIG. 23). Phosphor materials can be deposited in the stripes between the stripe dividers 2203. Alternatively, a fluorescent screen 101 having parallel fluorescent stripes made of different phosphor materials or other light-emitting materials under optical excitation can also be designed to allow for forming the fluorescent stripes on a flat surface first and then forming stripe dividers between two adjacent fluorescent stripes.

[00145] FIGS. 31A, 31B and 31C illustrate an example of a screen design with metalized stripe dividers and the fabrication process.

[00146] In FIG. 31A, a screen substrate or film 4110 is provided to support phosphor stripes. The substrate for film 4110 can be made from a range of materials, e.g., a polyester film (e.g., Mylar) or a composite film having multiple layers of dielectric materials, a prism film having a flat surface on which the phosphor stripes are formed and a structures surface with prism stripes. In one implementation, the thickness of the substrate or film 4110 can be around 25 microns or less. Phosphor stripes may be printed directly onto the substrate 4110 via a printing process. Alternatively, a strip mold can be used where the phosphor materials can be first applied to the mold to form phosphor stripes and the molded phosphor stripes are subsequently transferred to the substrate 4110.

Different phosphor stripes are separated from one another by a separation stripe gap between two adjacent stripes.

[00147] Next, a metal layer is deposited over the substrate 4101 and the phosphor stripes to completely cover the phosphor stripes (FIG. 31B). The separate gap between two adjacent phosphor stripes is either partially or completely filled with the metal material for the metal layer. Subsequently, a polishing process is performed to remove part of the metal material on top of the phosphor stripes and part of the phosphor stripes to expose the central portion of each phosphor stripe (FIG. 31C). Other than the central exposed portion, the metal material remains on the phosphor stripes. A polished surface is formed by the exposed phosphor stripes and the metal layer. The middle between two adjacent phosphor stripes may have a void dip or may be filled with polished metal. Notably, two adjacent phosphor stripes are separated by the opaque and reflective metal material used for the metal layer to prevent light from one stripe from entering an adjacent stripe. FIG. 31C shows that a void dip is formed above the metal at the middle between two adjacent phosphor stripes.

[00148] Various techniques may be used to remove the coated metal and part of the phosphor materials. For example, sanding, lapping, or cutting process may be used to remove the metal and phosphor materials from the peaks. Because the cross-section shape of the printed lines is approximately hemi-spherical the emission width for each color becomes wider with further lapping. A process may be developed which relies upon the rapid increase in surface area as lapping progresses to act as a natural stopping point for removing the material. Some micro-texture may be left on the planarized surface to create air gaps for subsequent lamination and the texture provides "high spots" for adhesion without full surface contact.

[00149] The screen structure shown in FIG. 31C can then be used to construct a screen 101 in various configurations. Specific examples are provided below.

[00150] FIG. 32 shows one design where the substrate or film 4110 is used on the excitation side. The void in the metal layer between two adjacent phosphor stripes, which faces the viewer, can be filled with an opaque black filter material such as a black paint to reduce reflection of light to the viewer (e.g., ambient light or other stray light).

5 **[00151]** FIG. 33 shows another design where the substrate or film 4110 is used to face the viewer side to transmit light to the viewer. A second substrate or film is engaged to the polished top surface on the excitation side of the phosphor stripes. If there is a void in the metal layer between two adjacent phosphor stripes, a reflective filler material can be filled in the void to reflect light back to the excitation side as feedback light for a servo control. Such as reflective filler material can be a reflective white paint or a reflective material having reflective beads. This design, different from the designs in FIGS. 28 and 30, provides larger area in each phosphor stripe facing the viewer side and uses the remained metal layer on each stripe to reflect emitted color light towards the viewer. This design may be used to improve the light throughput to the viewer.

15 **[00152]** FIG. 34 shows an example of a screen with metalized stripe dividers containing reflective beads. The substrate or film 4110 on which the phosphor stripes are formed is used to face the excitation side. The fabrication of this screen is different from the process shown in FIGS. 31A-31C. In fabrication the screen in FIG. 34, after the phosphor stripes are formed on the layer 4110 shown in FIG. 31A, a reflective filler material containing reflective beads or reflective white paint (e.g., BaSO₄) can be filled in the gaps between different phosphor stripes. Next, a metal layer is deposited over the phosphor stripes, the reflective filler material in

20
25
30
35

the gaps and the gaps to completely cover the phosphor stripes. Subsequently, a polishing process is performed to remove part of the metal material on top of the phosphor stripes and part of the phosphor stripes to expose the central
5 portion of each phosphor stripe. The reflective filler material remains covered by the deposited metal material. Referring back to FIGS. 29A and 29B, the above reflective beads can be implemented as a mixture of beads and a bead binder material where the bead binder material provides a
10 matrix in which the beads are distributed and supported.

[00153] While this specification contains many specifics, these should not be construed as limitations on the scope of an invention or of what may be claimed, but rather as descriptions of features specific to particular embodiments of
15 the invention. Certain features that are described in this specification in the context of separate embodiments can also be implemented in combination in a single embodiment. Conversely, various features that are described in the context of a single embodiment can also be implemented in multiple
20 embodiments separately or in any suitable subcombination. Moreover, although features may be described above as acting in certain combinations and even initially claimed as such, one or more features from a claimed combination can in some cases be excised from the combination, and the claimed
25 combination may be directed to a subcombination or a variation of a subcombination.

[00154] Only a few implementations are disclosed. However, it is understood that variations and enhancements may be made.

CLAIMS

What is claimed is:

1. A display screen, comprising:
a plurality of parallel screen layers which are engaged to form a planar stack and comprise:
a fluorescent layer absorbing excitation light at an excitation wavelength to emit visible light at a different visible wavelength; and
a prismatic layer comprising a plurality of prism elements which receive and couple the excitation light to the fluorescent layer.
2. The display screen as in claim 1, further comprising:
a low-index layer formed on a side of and in contact with the fluorescent screen that is opposite to the prismatic layer and having a refractive index less than a refractive index of the fluorescent layer; and
a screen layer in contact with the low-index layer and having a refractive index higher than the refractive index of the low-index layer.
3. The display screen as in claim 2, wherein:
the low-index layer is an air gap.
4. The display screen as in claim 1, wherein:
the fluorescent layer comprises a plurality of parallel fluorescent stripes; and
wherein the display screen further comprises a plurality of parallel stripe dividers each located between two adjacent fluorescent stripes.
5. The display screen as in claim 4, wherein:
the stripe dividers comprise a white paint that is optically reflective and opaque.

6. The display screen as in claim 5, wherein:
the white paint comprises a mixture of a resin with
either TiO_2 or Barium Sulfate.

7. The display screen as in claim 4, wherein:
each stripe divider comprises a fluorescent material that
emits fluorescent light at a wavelength different from the
excitation light and the visible light.

8. The display screen as in claim 4, wherein:
each stripe divider comprises a reflective metal coating.

9. The display screen as in claim 4, wherein:
at least three adjacent fluorescent stripes of the
plurality of the fluorescent stripes are made of,
respectively, a first fluorescent material to absorb the
excitation light to emit first visible light of a first color,
a second fluorescent material to absorb the excitation light
to emit second visible light of a second color, and a third
fluorescent material to absorb the excitation light to emit
third visible light of a third color.

10. The display screen as in claim 4, wherein:
each fluorescent stripe comprises a fluorescent material
that absorbs the excitation light and emits white light; and
wherein the screen layers further comprise a filter layer
comprising a plurality of parallel filter stripes each aligned
to a corresponding fluorescent stripe along a direction
perpendicular to the to the screen layers, and wherein the
fluorescent layer is located between the prismatic layer and
the filter layer, and

wherein at least three adjacent filter stripes are
respectively made of a first filter material to transmit first
visible light of a first color while absorbing light of other
colors including a second color and a third color, a second
filter material to transmit second visible light of the second
color while absorbing light of other colors including the

first and the third colors, and a third filter material to transmit third visible light of the third color while absorbing light of the other colors including the first and the second colors.

11. The display screen as in claim 4, wherein:

the screen layers further comprise a filter layer comprising a plurality of parallel filter stripes each aligned to a corresponding fluorescent stripe along a direction perpendicular to the screen substrate, the fluorescent layer located between the prismatic layer and the filter layer, and

at least three adjacent filter stripes are respectively made of a first filter material to transmit first visible light of a first color while absorbing light of other colors including a second color and a third color, a second filter material to transmit second visible light of the second color while absorbing light of other colors including the first and the third colors, and a third filter material to transmit third visible light of the third color while absorbing light of the other colors including the first and the second colors.

12. The display screen as in claim 11, wherein:

the screen layers further comprise a plurality of second parallel stripe dividers each located between two adjacent filter stripes.

13. The display screen as in claim 12, wherein:

the screen layers further comprise a dielectric layer between the fluorescent layer and the filter layer, and

the stripe dividers are in contact with the dielectric layer to separate the dielectric layer and the filter layer from each other by a gap.

14. The display screen as in claim 13, wherein:

the gap between the filter layer and the dielectric layer is filled with a low-index dielectric material having a refractive index less than a refractive index of the dielectric layer.

15. The display screen as in claim 13, wherein:

the gap between the filter layer and the dielectric layer is filled with air.

16. The display screen as in claim 4, wherein:

the screen layers further comprise a filter layer comprising a plurality of parallel filter stripes each formed between two adjacent stripe dividers to align with a corresponding fluorescent stripe between the two adjacent stripe dividers, the fluorescent layer located between the prismatic layer and the filter layer,

at least three adjacent filter stripes are respectively made of a first filter material to transmit first visible light of a first color while absorbing light of other colors including a second color and a third color, a second filter material to transmit second visible light of the second color while absorbing light of other colors including the first and the third colors, and a third filter material to transmit third visible light of the third color while absorbing light of the other colors including the first and the second colors.

17. The display screen as in claim 16, wherein:

the screen layers further comprise a dielectric layer between the prismatic layer and each fluorescent stripe and the dielectric layer has a refractive index less than a refractive index of the fluorescent stripe.

18. The display screen as in claim 16, wherein:

the screen layers further comprise a dielectric layer between each filter stripe and a corresponding fluorescent stripe.

19. The display screen as in claim 1, wherein:

the fluorescent layer comprises a uniform layer of a fluorescent material that absorbs the excitation light and emits white light;

the screen layers further comprise a filter layer comprising a plurality of parallel filter stripes, the fluorescent layer being located between the prismatic layer and the filter layer; and

at least three adjacent filter stripes are respectively made of a first filter material to transmit first visible light of a first color while absorbing light of other colors including a second color and a third color, a second filter material to transmit second visible light of the second color while absorbing light of other colors including the first and the third colors, and a third filter material to transmit third visible light of the third color while absorbing light of the other colors including the first and the second colors.

20. The display screen as in claim 1, wherein:

the screen layers further comprise a filter layer formed on one side of the fluorescent layer that is opposite to a side where the prismatic layer is located,

the filter layer blocks transmission of the excitation light and transmits the visible light with an attenuation that is uniform over a spectral range of the visible light.

21. The display screen as in claim 1, wherein:

the screen layers further comprise:

a selective blocking layer that transmits the visible light and blocks the excitation light, and

a neutral density filter layer that attenuates the visible light with an attenuation uniform over a spectral range of the visible light; and

the selective blocking layer and the neutral density filter layer are located at a side of the fluorescent layer that is opposite to the side where the prismatic layer is

located.

22. The display screen as in claim 1, wherein:

the prismatic layer is a first layer that receives the excitation light and is spaced from an adjacent screen layer by an air gap.

23. The display screen as in claim 1, wherein:

the prismatic layer comprises a plurality of parallel prismatic stripes, and

the fluorescent layer comprises a plurality of parallel fluorescent stripes that are perpendicular to parallel prismatic stripes.

24. The display screen as in claim 1, further

comprising:

a Fresnel lens layer placed on one side of the prismatic layer that is opposite to the side where the fluorescent layer is located, the Fresnel lens layer directing the excitation light to the prismatic layer.

25. A display screen, comprising:

a plurality of screen layers which are engaged to form a planar stack and comprise:

a fluorescent layer comprising a plurality of parallel fluorescent stripes and absorbing excitation light at an excitation wavelength to emit visible light at a different and visible wavelength,

a plurality of parallel stripe dividers each located between two adjacent fluorescent stripes, each stripe divider having side walls that are reflective and opaque to the emitted visible light to optically isolate two adjacent fluorescent stripes, and

a dielectric layer in contact with the stripe dividers and spaced from the fluorescent layer to form a gap between the dielectric layer and each fluorescent stripe.

26. The display screen as in claim 25, wherein:
the gap is filled with air.

27. The display screen as in claim 25, wherein:
the screen layers further comprise:
an entrance layer to receive the excitation light and
located on one side of the fluorescent screen that is opposite
to the dielectric layer, and
a filter layer on one side of the fluorescent layer where
the dielectric layer is located, and
the filter layer blocks transmission of the excitation
light and transmits the visible light with an attenuation
uniform over a spectral range of the visible light.

28. The display screen as in claim 25, wherein:
the screen layers further comprise:
an entrance layer to receive the excitation light and
located on one side of the fluorescent screen that is opposite
to the dielectric layer,
a selective blocking layer that transmits the visible
light and blocks the excitation light, and
a neutral density filter layer that attenuates the
visible light with an attenuation uniform over a spectral
range of the visible light; and
the selective blocking layer and the neutral density
filter layer are located at a side of the fluorescent layer
that is opposite to the side where the entrance layer is
located.

29. The display screen as in claim 25, wherein:
the screen layers further comprise:
a filter layer comprising a plurality of parallel filter
stripes each aligned to a respective fluorescent stripe along a
direction perpendicular to the screen layers, each filter
stripe of the filter layer being located between the gap and a
respective fluorescent stripe, and

at least three adjacent filter stripes are respectively made of a first filter material to transmit first visible light of a first color while absorbing light of other colors including a second color and a third color, a second filter material to transmit second visible light of the second color while absorbing light of other colors including the first and the third colors, and a third filter material to transmit third visible light of the third color while absorbing light of the other colors including the first and the second colors.

30. The display screen as in claim 29, wherein:

each filter stripe is formed between two adjacent stripe dividers and thus aligns with a corresponding fluorescent stripe between the two adjacent stripe dividers.

31. The display screen as in claim 30, wherein:

the stripe dividers comprise a white paint that is optically reflective and opaque.

32. The display screen as in claim 31, wherein:

the white paint comprises a mixture of TiO_2 or barium sulfate and a resin.

33. The display screen as in claim 30, wherein:

each stripe divider comprises a reflective metal coating.

34. The display screen as in claim 30, wherein:

each stripe divider absorbs the excitation light and emits fluorescent light at a wavelength different from the excitation light and the visible light.

35. The display screen as in claim 25, further comprising:

a Fresnel lens layer placed on one side of the dielectric layer that is opposite to the side where the fluorescent layer is located, the Fresnel lens layer directing the excitation light to the dielectric layer.

36. A display screen, comprising:

a screen substrate;

a fluorescent layer formed over the screen substrate and comprising a plurality of parallel fluorescent stripes, the fluorescent layer absorbing excitation light to emit visible light, wherein the excitation light and the visible light are at different wavelengths;

a plurality of parallel stripe dividers each located between two adjacent fluorescent stripes;

a dichroic layer formed over the screen substrate to receive the excitation light, wherein the dichroic layer transmits the excitation light and reflects the visible light.

37. The display screen as in claim 36, further comprising:

a dielectric layer having a plurality of dielectric stripes each placed between the dichroic layer and the fluorescent layer and between two adjacent stripe dividers.

38. The display screen as in claim 36, further comprising:

a filter layer formed over the screen substrate and comprising a plurality of parallel filter stripes each formed between two adjacent stripe dividers to align with a corresponding fluorescent stripe between the two adjacent stripe dividers, and wherein the fluorescent layer is located between the dichroic layer and the filter layer,

wherein at least three adjacent filter stripes are respectively made of a first filter material to transmit first visible light of a first color while absorbing light of other colors including a second color and a third color, a second filter material to transmit second visible light of the second color while absorbing light of other colors including the first and the third colors, and a third filter material to transmit third visible light of the third color while absorbing light of the other colors including the first and

the second colors.

39. The display screen as in claim 38, further comprising:

a dielectric layer having a plurality of dielectric stripes each placed between two adjacent stripe dividers and between the fluorescent layer and the filter layer.

40. The display screen as in claim 36, wherein:
the stripe dividers comprise a white paint that is optically reflective.

41. The display screen as in claim 40, wherein:
the white paint comprises a mixture of TiO_2 or barium sulfate and a resin.

42. The display screen as in claim 36, wherein:
each stripe divider comprises a reflective metal coating.

43. The display screen as in claim 36, wherein:
each stripe divider comprises a fluorescent material that emits fluorescent light at a wavelength different from the excitation light and the visible light.

44. The display screen as in claim 36, further comprising:

a second dichroic layer that transmits the visible light and reflects the excitation light, the second dichroic layer formed over the screen substrate, wherein the fluorescent layer is between the dichroic layer and the second dichroic layer.

45. The display screen as in 44; further comprising:
a dielectric layer in contact with the second dichroic layer, wherein the second dichroic layer is between the fluorescent layer and the dielectric layer.

46. A display screen, comprising:

a fluorescent layer comprising a plurality of parallel fluorescent stripes, the fluorescent layer absorbing excitation light to emit visible light, wherein the excitation light and the visible light are at different wavelengths;

an entrance layer formed on a first side of the fluorescent layer to receive the excitation light and to direct the excitation light to the fluorescent layer; and

a filter layer formed a second side of the fluorescent layer opposing the first side, the filter layer formed of a material that transmits the visible light with an attenuation uniform over a spectral range of the visible light.

47. The display screen as in claim 46, wherein:

the filter layer further blocks transmission of the excitation light.

48. The display screen as in claim 46, further

comprising:

a second filter layer formed a second side of the fluorescent layer opposing the first side, the second filter layer blocking transmission of the excitation light and transmitting the visible light.

49. The display screen as in claim 46, wherein:

the entrance layer comprises a prismatic layer which includes a plurality of prism elements.

50. The display screen as in claim 46, wherein:

the entrance layer comprises a dielectric layer with a flat surface to receive the excitation light.

51. A display screen, comprising:

a fluorescent layer that absorbs excitation light to emit visible light; and

a first layer on a first side of the fluorescent layer operable to transmit the excitation light and to reflect the

visible light, the first layer comprising a prismatic layer which comprises a plurality of prism elements.

52. The display screen as in claim 51, wherein:
the fluorescent layer comprises parallel fluorescent stripes and stripe dividers between the fluorescent stripes.

53. The display screen as in claim 52, wherein:
each stripe divider emits invisible fluorescent light under excitation by the excitation light.

54. A display screen, comprising:
a fluorescent layer that absorbs excitation light to emit white light, and
an array of color filters adjacent to the fluorescent layer to receive the emitted white light and to filter the white light to transmit colored light, each color filter transmitting a designated color and absorbing light of other colors, each designated color for one color filter being different from a designated color transmitted by a neighboring color filter.

55. The display screen as in claim 54, further comprising:
a first layer on a first side of the fluorescent layer to transmit the excitation light to the fluorescent layer and to reflect the visible light.

56. The display screen as in claim 55, wherein:
the first layer comprises a prismatic layer which comprises a plurality of prism elements. A display screen, comprising:
a plurality of screen layers which are engaged to form a planar stack and comprise:
a fluorescent layer comprising a plurality of parallel fluorescent stripes and absorbing excitation light at an excitation wavelength to emit visible light at wavelengths

different from the excitation wavelength,

a plurality of parallel stripe dividers each located between two adjacent fluorescent stripes, each strip divider being reflective and opaque to the emitted visible light to optically isolate two adjacent fluorescent stripes, and

a dielectric layer in contact with the fluorescent stripes and the stripe dividers to couple the excitation light into the fluorescent stripes,

a filter layer comprising a plurality of parallel filter stripes each aligned to a corresponding fluorescent stripe along a direction perpendicular to the screen layers, the fluorescent layer being located between the dielectric layer and the filter layer, wherein at least three adjacent filter stripes are respectively made of a first filter material to transmit first visible light of a first color while absorbing light of other colors including a second color and a third color, a second filter material to transmit second visible light of the second color while absorbing light of other colors including the first and the third colors, and a third filter material to transmit third visible light of the third color while absorbing light of the other colors including the first and the second colors,

a second dielectric layer between the fluorescent layer and the filter layer; and

a plurality of second parallel stripe dividers each located between two adjacent filter stripes and in contact with the second dielectric layer.

57. The display screen as in claim 56, wherein:

second parallel stripe dividers separate the transparent dielectric layer and the filter layer from each other by a gap.

58. The display screen as in claim 57, wherein:

the gap between the filter layer and the transparent dielectric layer is filled with air.

59. The display screen as in claim 56, wherein:

a facet of each second parallel stripe divider that faces away from the fluorescent layer is optically absorbent.

60. A display screen, comprising:

a first dielectric layer that transmits excitation light at an excitation wavelength;

a fluorescent layer comprising a plurality of parallel fluorescent stripes and absorbing the excitation light to emit visible light at a different and visible wavelength; and

a second dielectric layer spaced from the fluorescent stripes by an air gap, wherein the second dielectric layer at least partially transmits the visible light, and wherein the fluorescent layer is positioned between the first and second dielectric layers.

61. The display screen as in claim 60, wherein:

the second dielectric layer blocks the excitation light.

62. The display screen as in claim 60, wherein:

the second dielectric layer uniformly attenuates light in a visible spectral range.

63. The display screen as in claim 60, wherein:

the second dielectric layer blocks the excitation light and uniformly attenuates light in a visible spectral range.

64. A display screen, comprising:

a fluorescent layer comprising a plurality of parallel fluorescent stripes, each fluorescent stripe emitting visible light under illumination of excitation light that optically excites the fluorescent stripe; and

a plurality of parallel stripe dividers each located between two adjacent fluorescent stripes to separate the two adjacent fluorescent stripes,

wherein each stripe divider comprises beads that reflect

the excitation light as feedback light.

65. The display screen as in claim 64, wherein:
each stripe divider comprises a binder material in which the beads are supported.

66. The display screen as in claim 65, wherein:
the binder material has a refractive index less than a refractive index of the beads.

67. The display screen as in claim 65, wherein:
the binder material is a resin, and
the beads are made of a glass or plastic material.

68. The display screen as in claim 64, wherein:
each bead is coated with a partially transmissive and partially reflective coating.

69. The display screen as in claim 64, wherein:
one exterior portion of each bead is coated with a reflective coating.

70. The display screen as in claim 69, wherein:
the reflective coating is a metal layer.

71. A display screen, comprising:
a fluorescent layer comprising a plurality of parallel fluorescent stripes, each fluorescent stripe emitting visible light under illumination of excitation light that optically excites the fluorescent stripe;

a plurality of parallel stripe dividers each located between two adjacent fluorescent stripes to separate the two adjacent fluorescent stripes; and

a plurality of parallel prism stripes formed over and in alignment with the parallel stripe dividers, respectively, each prism stripe structured to reflect the excitation light as feedback light.

72. A display screen, comprising:

a substrate having a flat surface;

a plurality of parallel fluorescent stripes formed on the flat surface and separated from one another by a gap between two adjacent fluorescent stripes; and

a metal coating covering peripheral portions of each of the fluorescent stripes and the gaps over the flat surface between the fluorescent stripes to expose a central portion of each fluorescent stripe.

73. A method for making a display screen, comprising:

forming a plurality of parallel fluorescent stripes on a flat surface of a substrate, the stripes separated from one another by a gap between two adjacent fluorescent stripes;

depositing a metal coating to completely cover the fluorescent stripes and to cover the gaps between the fluorescent stripes over the flat surface; and

removing a layer of the metal coating and a portion of each fluorescent stripe to expose a central portion of each fluorescent stripe while maintaining at least the metal coating at peripheral portions of each fluorescent stripe.
